ON August 27th I was called to see a Turk, twenty-two years of age, who had had right inguinal hernia for ten years. The scrotum was now swollen, tense, and very tender, and the contents were irreducible. Ten days previously he had taken to his bed with chills, fever, and pain in the abdomen. Five days after the beginning of this illness (to use his own language) his "intestines came down and did not go back as usual." It seemed to me like strangulated hernia, but there was no vomiting and the bowels were acting quite regularly. On the second day I operated and evacuated about a pint of fœtid pus from the hernial sac which did not contain any intestine. The inguinal canal was firmly closed and there was no communication with the abdominal cavity. I washed out the sac and established free drainage, after which he improved very much for a week. Then he began to get worse, having fever and complaining of abdominal pain. In a few days I detected very marked swelling and dulness in the lower third of the abdomen, which was tender and gave all the signs of containing pus, while the upper two thirds were flat, natural, and not tender. I did not open the abdomen but continued fomentations and tonics with occasional doses of opium to relieve him. By this treatment the swelling and fluid disappeared in eleven days. The man is now going about and transacting his business as formerly.

I think this was a case of tuberculous peritonitis accompanied with tuberculosis of the sac. The interesting features to me were the rapid closure of the sac, the partial peritonitis, and the rapid disappearance of the fluid and inflammation from the abdominal cavity.

MEMBRANOUS LARYNGITIS, WITH HYPERPYREXIA FROM MALARIAL POISON.

BY CHARLES LLOYD WORRALL, L.R.C.P. LOND.

AT the cost of being considered long behind the times I am driven to designate the following as a case of "simple membranous" laryngitis in contra-distinction to diphtheritic laryngitis. This one is compelled to believe owing to the total absence of the usual symptoms of diphtheria. On Sept. 20th I was asked to see a child, two and a half years of age, who had been ailing for about five days, the symptoms notably being a very frequent cough of the characteristic "croupy" type with almost entire loss of voice. On examining the throat a very marked whitish membrane—not of the "wash-leather" type—was seen at the back of the throat implicating the larynx, the tonsils

Digitized by Google

and palate being quite free, and these parts remained quite free to the last. Until Sept. 23rd the child was treated in the usual way, when the dyspnœa at times became so very pronounced and inspiratory recession of the intercostal spaces so marked that on the evening of the same day, with the kind help of a colleague (Mr. P. C. Powrie), I performed tracheotomy. Vitality was so good that it was deemed advisable to give a few whiffs of chloroform. In a few minutes after the trachea was opened and a few free inspirations were taken all the urgent symptoms passed. On the following morning the child continued to do well, but about midday, without any warning, he was seized with a convulsion which lasted for a considerable time, notwithstanding a tepid bath, &c. Later in the afternoon the temperature was found to have run up to 108·9° F. A tepid bath reduced it a couple of degrees, but notwithstanding this the child soon got into quite a collapsed condition and died about 6 P.M. I should mention that the child never regained consciousness after the convulsion. Further, it should be stated that until the day after the operation there had never been anything like a high temperature and I would point out that but for the hyperpyrexia the case might perhaps have had a more happy termination. To explain more fully, the child came from a malarial district and I had attended him more than once for malarial fever, but the last time when I attended him for this complaint was many months ago. But notwithstanding this I do not exonerate myself for withholding quinine in the case and should I ever have to treat a case of this kind again in a malarial district I shall place quinine as the first drug on my list.

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv. Procœmium.

ROYAL INFIRMARY, NEWCASTLE-UPON-TYNE.

A CASE OF EXTRA-UTERINE FŒTATION; REMOVAL OF A FULLY-DEVELOPED DEAD CHILD, THE PLACENTA BEING LEFT; RECOVERY.

(Under the care of Mr. FREDERICK PAGE.)

THE danger of severe hæmorrhage after removal of the placenta in cases of extra-uterine fœtation results from the fact that the tissues of the placental site have no power of contraction, so that the vessels continue to bleed freely. When the fœtus dies the circulation in the placenta ceases, first in the fœtal vessels and later in the maternal vessels, so that after a certain time the placenta may be removed without risk of severe loss of blood. In the interesting case reported below this thrombosis of the placental vessels had not occurred, although a fortnight had elapsed from the death of the fœtus, for severe hæmorrhage threatened when the removal of the placenta was attempted. A further point of interest in the case is the absence of any lochia or decidual cast. For the notes of the case we are indebted to Dr. J. D. Wardale, surgical registrar.

A woman, aged thirty-nine years, was on July 7th, 1898, admitted into the Royal Infirmary, Newcastle-upon-Tyne, under the care of Mr. Frederick Page. She stated that she had considered herself pregnant, but had gone ten months and parturition had not taken place. Eighteen years ago she had her only child, the labour being normal. There was no history of floodings or miscarriages. Menstruation had been quite regular until ten months previously, when it suddenly ceased; morning sickness and enlargement of the breasts followed, causing her to consider herself pregnant. Two and a half months later she was suddenly seized with severe cramping pains in the abdomen and felt cold and shivered, but she did not vomit, nor was there any loss of blood from the vagina. This attack lasted twelve hours. A week later she had a similar but more severe attack, on account of which she was confined to bed for three months. Five months after the cessation of the menses she felt "quickening"; meanwhile, the abdomen was steadily increasing in size and the breasts contained milk. Six weeks before admission, being, according to her calculations, eight and a half months pregnant, she experienced severe intermittent pains in the front of the abdomen. A month later she again felt similar pains with greater severity, and at this time there was also a slight blood-stained vaginal discharge. Since then these pains had recurred about every ten minutes and in consequence she had had very little sleep during the fortnight before admission. During the past six weeks the breasts had gradually diminished in size.

The patient looked thin, sallow, and exhausted, the pulse was 120, feeble and of low tension, and the temperature was 100° F. The abdomen was hugely and uniformly distended. A tense cystic mass, in which fluctuation could be readily elicited in all directions, extended from the pubes to within about 1 in. of the ensiform. The whole mass became tense at times of pains; at such times also a hard, ball-like mass of the size of a closed fist could be seen to contract to the right of the middle line, about 5 in. above the pubes. Nothing representing the fœtal limbs could be felt. On repeated auscultation no fœtal heart-sounds were heard but a loud and distinct placental souffle was made out on the left side below the level of the umbilicus. The breasts were soft and flaccid; a very little milk could be expressed with difficulty. The vagina was soft and œdematous, extending in a forward direction behind the pubes, but the os could not be reached. The posterior vaginal wall bulged as if with fluid, through which a hard mass, like the fœtal head, was readily felt and could be pushed up through the fluid, giving distinct *ballottement*. A catheter on being passed into the urethra went in a backward direction; the bladder contained very little urine; the urine was alkaline, very foul, and contained mucus, pus, and phosphates. Cystitis was present.

On account of the patient's bad condition, owing to sleeplessness, frequent repetition of pains, and cystitis, she was kept at rest, sleep was induced by the administration of opium, and the bladder was frequently washed out. The temperature meanwhile fluctuated between 97·6° and 100°. On July 19th, twelve days after admission, the patient was anæsthetised, chloroform being used, and on introducing the hand into the vagina the cervix was felt high up, 1½ in. above the pubes, the os being soft and patulous, readily admitting the forefinger. An incision was made in the middle line extending from 4 in. above the umbilicus to 2 in. above the pubes. The enlarged uterus, of about the size of a cocoanut, presented immediately below the umbilicus and to the right of the middle line. Behind, above, and around this was a tense cyst of a bluish colour, covered by the thinned omentum, which was adherent and very vascular. The omentum was partially detached, a trocar was inserted into the cyst, and a large quantity of grumous blood-stained fluid was removed which had no smell of putrefaction. The opening in the cyst wall was now enlarged, a leg was seized, and a dead full-term fœtus was removed. The cord was torn through close to the umbilicus. The placenta was found firmly adherent to the left side of the sac wall; it was not disturbed. The intestines, small and collapsed, were found above and to the right of the sac. The edges of the opening into the cyst were closely sutured to the lower part of the abdominal incision and the cavity was packed with gauze. The upper portion of the incision, that communicating with the general peritoneal cavity, was packed off with gauze and was carefully closed with sutures. As far as could be made out this large sac was entirely retro-peritoneal. The fœtus weighed 6½ lb.

After the operation the patient was greatly troubled by "after pains," which were controlled by opium. On July 20th, the day following the operation, the evening temperature reached 102·2°. On the 21st the gauze packing was removed, no hæmorrhage occurring, and the cavity was repacked. On the 22nd the wound was dressed daily and the cavity was douched with corrosive sublimate (1 in 10,000) and subsequently with a lotion of permanganate of potassium. On the 24th the finger was gently inserted under the edge of the placenta and the cavity at once filled with dark venous blood. The packing was again firmly introduced. On the 31st a further attempt was made to separate the margin of the placenta and the cavity again promptly filled with blood. The hæmorrhage was readily stopped by packing. The

Digitized by Google

placenta gradually came away piecemeal, the last remnants separating on August 11th. Since the operation there had been no lochial discharge and no decidual cast of the uterus had been thrown off. The temperature meanwhile had been fluctuating between 98·6° and 100°, on one occasion (August 2nd) reaching 102·2°. On and after August 16th the temperature remained normal. On August 26th the patient was discharged in good condition with a minute sinus at the lower extremity of the wound. She has been seen at a more recent date healed and in good health.

Remarks by Mr. PAGE.—The point to which I wish particularly to direct attention is the treatment of the placenta. The child had certainly been dead for twelve days before the operation, but the placenta remained "quick." Some twenty years ago a case very similar to the one reported occurred in the Royal Infirmary, Newcastle-upon-Tyne. The child was beyond term and dead at the time of the operation. The placenta was left *in situ*. A few days after the surgeon removed the placenta and the woman died at once from uncontrollable bleeding. I am satisfied had I removed the placenta either at the time of the operation or some days later that my patient too would have bled to death. It is stated in Bland Sutton and Giles's work on "Diseases of Women," 1897 edition, p. 248: "If the fœtus dies before the operation is attempted the placenta can be removed without risk of hæmorrhage." I think this dictum requires qualification.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

Fibrinous or Membranous Rhinitis and its Relation to Diphtheria.

A MEETING of this society was held on Oct. 25th, the President, Mr. BRYANT, being in the chair.

Dr. H. LAMBERT LACK read a paper on Fibrinous or Membranous Rhinitis and its Relation to Diphtheria. Fibrinous rhinitis, first described by Schuller in 1871, was defined as a subacute or chronic affection of the nose, characterised by a fibrinous or membranous exudation on the nasal mucous membrane. The great interest of the affection lay in its connexion with diphtheria, the older observers considering the diseases quite distinct, while more recent observers, relying on the results of bacteriological examination, claimed that fibrinous rhinitis was merely a mild manifestation of diphtheria. Cases of the disease were shown to be very common, forming no less than 2½ per cent. of all the children attending Dr. Lack's hospital practice. A brief analysis was then given of the symptoms presented by 36 cases of the affection. The disease was shown to be essentially one of children and to occur most frequently in the autumn months. The chief symptoms were purely local, such as nasal obstruction and discharge, excoriation of the nostrils and upper lip, occasional epistaxis, &c.; sometimes sore-throat was seen, presenting peculiar characteristics, which were described. The affection was very chronic, lasting on an average from six to eight weeks or more. General symptoms were seen to be very mild and sometimes were altogether absent. Many cases were not seen until very late in the disease; others probably were often overlooked even by competent observers; and some probably were never seen at all, the children, not being in any way ill, continued to attend school, &c., as usual. There was complete absence of all paralytic sequelæ. A brief sketch was then given of nasal diphtheria and special attention was drawn to cases in which a purulent nasal discharge persisted often for many weeks after an attack of true faucial diphtheria. The symptoms of the two diseases, fibrinous rhinitis and true nasal diphtheria, were then briefly contrasted. The results of bacteriological examination carried out in 33 cases were then reported. The true Klebs-Löffler bacillus was constantly present, generally in pure culture, sometimes mixed with pyogenic cocci, sarcinæ, &c. It was usually of the large variety, and its identity was proved by its morphology, by its growth on various culture media, &c. It was further shown to be of full virulence on animals, to produce virulent toxins, and to be neutralised by antitoxins. Further, it was shown to be capable of living for several months on culture media and by its vigorous growth to crowd out other organisms if present. Finally, the surroundings of the patients were examined, all sources of diphtheria sought for, and, as far as possible, all persons with whom the patients came into contact seen and examined both clinically and bacteriologically. A previous history of diphtheria was found in connexion with one case only. The disease was found to be very infectious, however; often it gave rise to itself (9 cases occurred in four families), and often to mild sore throat, 25 instances of which occurred in 11 families. The Klebs-Löffler bacillus was also found in the throats of healthy people who had been in association with these cases. A comparative investigation showing the frequency with which the bacilli were found in healthy noses was then described, and statistics of similar investigations on both healthy noses and throats and on cases of non-diphtheritic sore throat were quoted. The conclusion was arrived at that fibrinous rhinitis was a mild variety of diphtheria, the difference in the clinical manifestations apparently depending on some differences in the organisms associated with the Klebs-Löffler bacillus. The diagnostic value of the presence of the bacillus in sore throats which did not clinically appear to be diphtheria was also discussed and was considered to be very slight.

Dr. ALLAN MACFADYEN said that the association of the Klebs-Löffler bacillus with membranous rhinitis was now established, but it certainly was at first sight puzzling to find this bacillus present in this chronic rhinitis, in true diphtheria, and even in normal throats. There were probably several factors in infection. 1. The properties of the bacillus. It had been shown that the bacilli obtained by culture from true diphtheritic throats varied greatly in virulence. During convalescence, too, it had been shown that the bacillus altered in form and became shorter and stouter—the so-called "pseudo-diphtheria bacillus." By artificial means also the virulence of a culture could be degraded or intensified. 2. The condition of the tissues. 3. The presence and virulence of associated pyogenic organisms might lower the vitality of the tissues and facilitate the entrance of the diphtheria bacilli.

Mr. T. D. LISTER said that he had examined the nasal mucus of 125 children at the East London Hospital for Children. Of these 69 had some nasal discharge, watery, muco-purulent, or hæmorrhagic. These hæmorrhagic cases all gave pure cultures of the Klebs-Löffler bacillus. There were 39 children in whom the bacillus was found, and of these 10 were free from any nasal discharge whatever. Some were sent home and some were isolated in the hospital, but in no case did ordinary cases of diphtheria arise from these children coming in contact with others. He had examined 2 cases post mortem. In 1 there was a creamy exudation on the nasal mucosa as described by Dr. Lack, in the other there was nothing.

Dr. E. W. GOODALL said that it was well known that the Klebs-Löffler bacillus was present in very different conditions as, e.g., in the sore throat of scarlet fever and in healthy people. But the evidence of a causal connexion between this bacillus and diphtheria was too strong for it to be given up. He did not understand whether there had been definite membrane in Dr. Lack's cases. There was a form of nasal discharge occurring after scarlet fever which was very obstinate. Dr. Todd had found the Klebs-Löffler bacillus present in all of 51 cases he examined, corresponding to 700 or 800 cases of scarlet fever admitted. None of these gave rise to any case of diphtheria among other patients. But even when a case of true diphtheria (as shown by subsequent paralysis) got into a scarlet fever ward and was unrecognised for some time, it often did not infect scarlet fever cases. He asked if any of the cases had been treated with antitoxin, as in the cases of nasal discharge after scarlet fever the trouble stopped in a day or two if antitoxin was administered. Dr. Lack's description of true nasal diphtheria rather described forms in which it extended from the pharynx. He thought that when membrane was confined to the larynx or the nose constitutional symptoms were less severe, possibly because absorption of the toxins was less easy from those surfaces. He still thought that a case of sore throat in which Klebs-Löffler bacilli were present should be isolated and treated as diphtheria.

Mr. C. R. LYSTER mentioned a case in which a boy who was regarded as having only a slight cold in the head and without being himself ill brought the disease from a school

Digitized by Google

and communicated it in a virulent form to his mother and sisters, who died from it.

Dr. LACK, in reply, said that the throat was affected as well as the nose in his cases. In describing true nasal diphtheria he had drawn his picture from cases associated with faucial diphtheria. There was membrane on the nasal mucous membrane in his cases. This could only be seen on careful examination with a mirror as it did not affect the vestibule.

MEDICAL SOCIETY OF LONDON.

Abdominal Section for External Injury.—Venesection in Acute Pneumonia.

A MEETING of this society was held on Oct. 24th, Dr. KINGSTON FOWLER, Vice-President, being in the chair.

Mr. MARMADUKE SHEILD read a paper on four cases of Abdominal Section for External Injury not accompanied by Wound. After referring to the extreme difficulty of deciding how to act in this class of cases he related firstly the case of a boy, eleven years of age, who was run over by a cab and showed all the signs of grave abdominal injury, with serious collapse, which did not pass off. The abdomen was opened and found to be distended with blood, like a ruptured extra-uterine gestation. The source of hæmorrhage was found in a tear of the mesentery, which was repaired. The patient made a rapid and complete recovery. The next case was similar—a boy was run over by a heavy vehicle. The abdomen was found full of blood and the jejunum was torn quite across. A resection of intestine was rapidly done, end-to-end anastomosis being employed, and the mesentery was repaired. The case proved fatal and after death a second rupture which had escaped observation at the operation was found in the transverse duodenum, which was the source of the fatal peritonitis. The resected intestine had joined and held water under considerable pressure. The third case was a desperate one of ruptured liver in a boy, sixteen years of age, and was related to show the success of the treatment of the hæmorrhage in these injuries by plugging with iodoform gauze. The last case was very interesting. A woman, sixty-one years of age, was run over across the lower abdomen and showed grave signs of injury, together with hæmaturia. The bladder, however, held injected boric fluid and the diagnosis was made that it was intact. Blood, however, returned with the injection. The collapse and serious symptoms rather got worse than better and the abdomen was opened. There was some blood-stained fluid in the pelvis. The source of bladder trouble was apparent in a large ecchymosis of the size of a halfpenny on the posterior aspect of the fundus, just where rupture so commonly occurs. Careful examination showed that no actual perforation existed. The liver, spleen, and renal regions were palpated, but nothing more was found. After the operation the patient became feverish and maniacal. The symptoms were of the most puzzling nature and pointed to some pyæmic process, though its cause was not even guessed at. After death a fæcal abscess was found tracking up in the retro-peritoneal tissue towards the right kidney. This originated in a small rent on the posterior surface of the cæcum. It was peculiarly unfortunate that this had not been detected during life as it admitted of such easy repair. In conclusion Mr. Sheild discussed the indications for these operations. The symptoms of ruptured kidneys and bladder were generally to be demonstrated and the rules of treatment were tolerably clear. It was in ruptured intestine and mesentery, injuries of the liver and spleen and of the sympathetic nerves, that the greatest difficulties arose. As a general rule, when, after a severe abdominal injury, the symptoms were progressively grave, and especially if vomiting and abdominal distension began to come on, exploration was indicated. The mortality would be in direct proportion to the gravity of the injuries; the fatal operations are merely failures to save a life otherwise certainly doomed. It was of the utmost importance that these cases should be related. Only by accumulated experience could rules of practice be formulated.—Dr. KINGSTON FOWLER said it was interesting to notice that in several of Mr. Sheild's cases there was more than one lesion, a circumstance which made a full diagnosis extremely difficult. In cases of chronic obstruction it was also often found that there was more than one growth or other cause of obstruction. He asked whether in the cases of rupture of the intestine there was obliteration of the liver dulness. He had formerly thought that after perforation of a chronic ulcer the disappearance of hepatic dulness was always followed by a fatal issue, but he mentioned a case in which apparently perforation of a chronic ulcer occurred. After some hours the liver dulness became obliterated, and both he and a surgical colleague were quite convinced that perforation had occurred. The patient refused operation and the normal dulness gradually reappeared, recovery taking place.—Mr. G. R. TURNER mentioned a case of traumatic volvulus occurring in a boy who fell 12 ft., striking his abdomen against the pole of a boat. There was no wound, but the abdomen was explored twenty-four hours later. The volvulus was found and released and the boy made a good recovery. Since then he had seen several cases of injury of the viscera without external wound. In the first there was abundant hæmorrhage from a small rent in the under surface of the right lobe, which was plugged, but the condition of the patient was already very grave and he did not survive. In the second case a man who was carrying a heavy weight received a blow on the abdomen rupturing the small intestine. This was found and repaired, and a hernia from which he suffered was operated on at the same time and he did well. Another patient was admitted suffering from severe collapse and vomiting. He improved for a time but the vomiting returned and the abdomen was explored. A small tear was found in the under surface of the liver, and in addition there was enormous extravasation of blood in the retro-peritoneal tissue. Vomiting persisted and he died from exhaustion caused by vomiting ten days later. The kidney was found at the necropsy to have been crushed to a pulp. A week later another man was admitted with symptoms of rupture of the kidney. The abdomen was opened in the linea semilunaris. There was no blood in the peritoneal cavity, but there was again extensive retro-peritoneal hæmorrhage. The kidney was found to be extensively torn and was enucleated, the patient making a good recovery. Although he held strongly the view that in cases of grave injury surgical exploration should be resorted to the surgeon should exercise some caution in coming to a decision, remembering that in the old days some patients did recover under expectant treatment, as was shown by specimens exemplifying repair after injury of various organs to be seen in all museums.—Dr. F. LUCAS BENHAM mentioned the case of a boy who fell striking his abdomen against the kerb. There was pain about the cæcum and severe peritonitis, with symptoms of obstruction and stercoraceous vomiting. He was treated by leeching, the free administration of mercury internally and externally, and afterwards with small doses of turpentine. He recovered without surgical assistance.—Mr. F. C. WALLIS said it was interesting that no gangrene of the intestine had resulted in the case of rupture of a mesenteric artery. The influence of injury of the solar plexus in causing part of the condition of shock must not be overlooked. He mentioned a case which occurred in Germany where hæmorrhage from the liver from a stab was successfully treated by suturing. In cases of rupture, however, he was afraid the walls would not hold.—Mr. W. H. BATTLE insisted on the importance of watching cases of abdominal injury from hour to hour, as grave symptoms were often delayed and came on suddenly. No group of symptoms could be relied on to indicate particular lesions. In cases of rupture of the intestine sometimes the symptoms were clear and unequivocal, but often they were masked. He mentioned such a case in which a man was admitted after being run over. He was free from pain, anxiety, and fever for four days, and then the temperature suddenly ran up and he died in a few hours. At the necropsy a rupture of the small intestine was discovered. The amount of shock afforded little guide as to the severity of the visceral injury. He asked Mr. Turner how long had elapsed after the injury before he operated on the case of ruptured intestine.—Mr. TURNER stated that he operated about eight hours after the accident.—Mr. SHEILD, in reply, agreed as to the necessity for caution in deciding to explore. But if the collapse did not pass off, vomiting continued, and the abdomen became distended, delay was dangerous. He thought that Dr. Benham's case might very well be one of appendicitis lit up by the injury. In contrast to that case he mentioned one in the practice of another surgeon where a woman fell and bruised the right side of the abdomen. There were symptoms pointing to injury of the cæcum, but no operation was performed. She improved for a time but

Digitized by Google

a fæcal abscess formed, no doubt the result of a small rupture, and she died from pyæmia. He did not place very much reliance on examining for dulness. The abdominal tenderness usually precluded careful percussion, and even when fluid was present, unless it were encysted or in great quantity, its presence was often masked by the distension of the intestines. The disappearance of the hepatic dulness might, he thought, be brought about by intestinal distension as well as by free gas in the peritoneal cavity.

Dr. F. LUCAS BENHAM read a paper on the Advantages of Venesection in Acute Pneumonia, with Cases in Illustration. It was based on the report of 19 cases in which venesection had been successfully performed. All these cases were severe ones and in several life was undoubtedly saved by this means. The series included some cases of pneumonia complicating influenza and phthisis. Reference was also made to the beneficial employment of leeches in some forms of pneumonia in children, particularly that which complicates whooping-cough, and is very apt to be fatal. Additional cases were mentioned where death occurred notwithstanding bleeding or where death might have been averted if recourse had been had to blood-letting. The guiding principles laid down were that though venesection affords great relief in most cases of acute pneumonia from the earliest stages, and if performed in moderation never does the slightest harm, yet that, as cases of moderate severity recover by simple means only, venesection is indispensable only in severe and dangerous cases, the object aimed at being to convert a severe form of the disease into a mild one—i.e., to subdue the over-intensity of the morbid processes, the chief indications to follow after noting the severity of the initial rigor being a rapidly-increasing frequency of the pulse and nervous disturbance marked by sleeplessness and wandering. As pneumonia is a disease the symptoms of which increase in intensity from day to day until the crisis, the progress of this intensity may be checked or stayed by blood-letting if it is advancing too fast and thus betokens danger. It was possible that greater good might be done by bleeding at the very beginning of the disease, which might be cut short thereby; but it was generally useless to delay it till the last moment, when the patient was dying from the formation of clots in the heart.—Dr. KINGSTON FOWLER said that it was now half a century since the antiphlogistic pathological theories had been laid aside. It was possible that the pendulum had swung too far in the other direction. But personally, while he quite recognised that venesection had a definite value as a therapeutical weapon, he did not go as far as Dr. Benham in his recommendation of its use in pneumonia, although he admitted that his experience of its employment in that condition was limited. The condition which called for it was distension of the right side of the heart, especially in cases of chronic bronchitis with emphysema. He mentioned such a case in which a patient was greatly relieved by free hæmorrhage from the dorsalis pedis artery which was unintentionally included in an incision intended to relieve the patient's anasarca. It was also of undoubted value in relieving for a time the pain of aneurysm.—Dr. B. B. JOLL said that he had practised formerly in a district where periodical bleeding during health was the custom and where venesection was the routine practice in pneumonia and other fevers. The results were almost uniformly good.—Dr. LUCAS BENHAM agreed as to the value of venesection in cases of bronchitis, but he had intentionally confined himself to the treatment of pneumonia in his paper. He thought that venesection would be valuable in several grave diseases such as plague, hydrophobia, and the severer forms of malaria.

OPHTHALMOLOGICAL SOCIETY.

Glioma of the Optic Nerve.—Tension of the Eye in Irido-cyclitis.—Exhibition of Specimens.

THE first ordinary meeting of the session was held on Oct. 20th, Mr. H. R. SWANZY, President, being in the chair.

Mr. J. F. BULLAR and Mr. C. DEVEREUX MARSHALL communicated a paper on Glioma of the Optic Nerve. The case upon which it was based was that of a woman, aged thirty-seven years, who noticed nothing the matter until 1889, when the left eye became more prominent than natural. It continued to become more and more pushed forward until 1895, when Mr. Bullar operated and removed the tumour with the eyeball attached. Immediately behind the globe the optic nerve was of normal size for a distance of 15 mm. It thus formed a pear-shaped swelling 50 mm. long and 20 mm. wide. A cyst-like cavity was found inside this which contained straw-coloured fluid. On opening it the interior was found to be rough and vascular and had a fatty appearance. The tumour was encapsuled. The optic nerve was completely lost as soon as it entered the tumour, and it was not again seen at the posterior part, as the growth extended at least as far as the optic foramen and was cut across behind. The patient did quite well and had since married and was in good health. The tumour was proved by microscopic examination to have originated in the neuroglia; Mr. Bullar and Mr. Marshall have therefore termed it a glioma of the nerve. The eye was normal. In the literature on the subject 130 cases of growths of the optic nerve were recorded, and the results of these showed that these tumours were of slow growth, but should be classed as malignant, as they were liable to extend into the brain, although metastases had not been found in any case. The question of growths of all sorts found in the optic nerve was discussed, and although the different terms applied to them were legion, yet Mr. Bullar and Mr. Marshall were strongly of opinion that the majority of them would fall into three groups: (1) those originating in the neuroglia, which should be termed "gliomata"; (2) those originating in the dural sheath, "sarcomata"; and (3) those originating in the pial sheath, "endotheliomata." Mr. Bullar added that there had been no difficulty in removing the tumour. As soon as the conjunctival sac was opened the finger passed readily into the orbit and the tumour was easily defined; it was not necessary to clear out the orbit. The posterior section of the growth was made as close to the apex of the orbit as possible, but the tumour was cut through so that some portion of it must have been left behind. It would have been quite easy to remove the whole of it, leaving the eye behind, but in the stretched condition of all the parts he had not thought this advisable.—The PRESIDENT remarked upon the rarity of tumours of the optic nerve. He only remembered seeing one case.—Mr. J. B. LAWFORD referred to a case published by Mr. Rockliffe in which part of the tumour had been left in the orbit without ill consequences.—Mr. TREACHER COLLINS commented on the great variety of names which had been given to this form of tumour. He thought the best classification was the anatomical one—those originating in the sheaths of the nerves and those starting in the nerve itself. The optic nerve was a prolongation of the brain substance and gliomata of the optic nerve resembled those of the brain in structure rather than those of the retina, which approached the embryonic type in their round-celled formation.

Captain H. HERBERT, I.M.S., made a communication on the Tension of the Eye in Irido-cyclitis based on observation of 144 eyes affected with the disease. In the majority of attacks, more especially in the milder attacks, the tension was, as in simple hyperæmia of the iris and ciliary body, reduced, the reduction lasting, as far as the evidence went, at least as long as any ciliary injection remained. In other cases a period of high tension of very variable duration came on. The high tension appeared to be due to blockage of the normal outlets from the anterior chamber, and the eyes chiefly affected were (1) those very severely attacked with copious exudation; and (2) eyes perhaps lightly attacked but predisposed to glaucoma, as shown by shallow anterior chamber in the sound fellow eye and by more or less advanced age of the patient. In these high tension cases the anterior chamber was deepened and the pupil slightly dilated. In the most intense inflammations the plus tension rapidly gave way to a softening, which might be permanent and which indicated atrophy of the ciliary body. The mild attacks, which were little removed from primary subacute glaucoma, were of interest because of difficulties in diagnosis and in treatment. There were no grounds for attributing high tension to cyclitis as distinguished from iritis.—Mr. PRIESTLEY SMITH said that the principles enunciated by Captain Herbert were now generally accepted. There were two processes, mutually antagonistic, concerned in the regulation of tension in irido-cyclitis: one was the suppression of secretion reducing the tension, the other was the formation of an albuminous exudation hindering filtration and raising the tension. He had been glad to hear in this paper of the value of the tonometer he had introduced; after longer experience he thought it very valuable if its limitations were recognised. He had made some experiments on tension some years ago in which a perfectly limpid

Digitized by Google

albuminous fluid obtained from a serous cavity had been injected into an eye of a cadaver and normal saline solution into the other. In the former the tension was raised, in the latter it was not raised, showing that albuminous fluids will not filter through animal membranes.

The following living and card specimens were shown:—

Mr. R. M. GUNN: A case of Retinal Disease.

Dr. R. D. BATTEN: Superficial Central Choroiditis.

HARVEIAN SOCIETY OF LONDON.

Congenital Affection of the Heart. — Enlargement of the Spleen. — Pulmonary Osteo-Arthropathy. — Exhibition of Cases.

A MEETING of this society was held on Oct. 21st, the President, Dr. JAMES F. GOODHART, being in the chair.

Dr. ROBERT MAGUIRE showed a case of Congenital Affection of the Heart in which he thought the lesion was imperfection of the septum ventriculorum. This was so far the most common of the congenital defects of the heart causing symptoms, that all others might for clinical purposes be ignored. Even in the absence of cyanosis the condition of the heart could be diagnosed by the physical signs and especially by the character of the systolic murmur which was always present and which, Dr. Maguire asserted, was always heard best along the line of the interventricular septum, diminishing rapidly in intensity when this line was left, even though the murmur could still be heard in every part of the chest. Dr. Maguire stated that imperfection of the septum might be due to two causes: (1) intra-uterine endocarditis affecting the pulmonary orifice and so preventing, by increased tension in the right ventricle, the due formation of the septum; or (2) deficient developmental energy during the formation of the septum, without any cardiac disease. These two conditions, he asserted, could be diagnosed clinically, for while in the second condition there was present merely the murmur he had described, in the first there was also observed a continuation of the murmur to the left along the line of the pulmonary artery. The occasional absence of cyanosis in such cases was due to the fact that the tension in the left ventricle might be sufficient to prevent access of venous blood to its own cavity, admixture taking place only in the right ventricle, where it was of no consequence. When, however, by reason of bronchitis or some similar respiratory trouble, the tension in the right ventricle was increased, venous blood passed through the septal opening on to the left ventricle and caused cyanosis. It was wonderful how great a deficiency of the septum was compatible with life. In one case which he had observed for some eight years, and in which cyanosis often disappeared for considerable periods, he had found at the necropsy practically only one ventricle, the septum being represented by a small semilunar ridge near the apex of the heart.

Dr. MAGUIRE also showed a case of Congenital Heart Disease and made remarks on the varieties of such malformations.

Dr. GOW expressed surprise at the statement that the disease was so rare. He inquired whether the unilateral clubbing observed in cases of one-sided chest lesions, such as collapse of the lung from old empyema, was of the same nature as the cases exhibited.

Dr. LESLIE THORNE, referring to Dr. Maguire's remarks on congenital heart disease, asked him if he would kindly explain his reason for diagnosing previous intra-uterine inflammation in cases where the systolic murmur was conducted along the line extending from the second left costal cartilage upwards and outwards towards the left clavicular region, and congenital malformation where the murmur was not so conducted.

Dr. A. P. LUFF showed a case of Great Enlargement of the Spleen due to Hyperplasia and Fibrosis. The patient, a woman, aged fifty-three years, was first admitted into St. Mary's Hospital in June, 1896, when the spleen reached on the left side to the left anterior superior spine of the ilium and on the right side 1 in. to the right of the umbilicus. Since then it had gradually enlarged until at the present time it reached from 2 to 3 in. to the right of the umbilicus and downwards to the brim of the pelvis. For the past two and a half years the red blood corpuscles had averaged from 2,700,000 to 3,540,000 per hæmic unit while the proportion of white corpuscles to red had throughout been normal. There was no history of ague, malaria, of syphilis. The liver and lymphatic glands generally were normal.

The PRESIDENT alluded to the acute arthritis which sometimes complicates phthisis and is usually regarded as rheumatic. He asked whether the first conditions in Pulmonary Osteo-arthropathy might not be due to similar but chronic forms of arthritis. He drew attention to the analogy between acromegaly and pulmonary osteo-arthropathy and asked whether changes in the pituitary body had been found in the latter affection.

Dr. LEONARD GUTHRIE showed, for Dr. JAMES TAYLOR, a boy, aged seven and a half years, suffering from the congenital form of Myopathy. His parents were then healthy. The patient was the youngest of four, of whom the eldest was alive, aged twelve and a half years. The others died shortly after birth. The patient was a full-term child. He could not walk until he was five years of age and could never walk more than a few steps. His legs had not become thinner lately but his arms had wasted. He could never use a knife and fork. He was mentally bright. There was no facial affection. The special senses and sensation, the heart, the lungs, and the sphincters were normal. Movements of the head and neck were normal. There was no local enlargement of the muscles of the arm, but all were small. The middle and lower parts of the trapezii were wasted. The upper parts were normal. The supra- and infra-spinous fossæ were flattened on both sides. There was complete atrophy of both pectorales majores except a few of the lowest fibres on the left side. The serrati magni were small on both sides. The latissimi seemed absent on both sides. The diaphragm and intercostals seemed normal, the abdominal muscles were fair, and the spinal muscles were weak. The legs were very weak. He could carry out all movements as he lay in bed, but very feebly. He could only walk a few steps. The muscles of the leg were all very small and the knee-jerks were absent.

Mr. STANSFIELD COLLIER showed a man, aged seventy-three years, who after recovering from prostatectomy was suddenly seized with Pain in the Left Eye accompanied by proptosis. The symptoms subsided but again returned, and at the present time there was considerable protrusion of the left eyeball, together with the presence of a firm, tender swelling in the left temporal region. The fundus oculi was normal. His mental condition had recently deteriorated, but otherwise there were no definite cerebral symptoms. Mr. Collier believed that the swelling in the temporal region was malignant and that the sudden onset of symptoms was occasioned by hæmorrhage into a new growth.—The PRESIDENT agreed that a new growth probably existed in Mr. Collier's patient. He alluded to the case of a public speaker who was suddenly attacked by pain in the head with marked proptosis whilst in the act of addressing a meeting. A loud bruit was audible all over the skull and he (the President) believed that an arterio-venous aneurysm had formed in the neighbourhood of the cavernous sinus.

Mr. COLLIER also showed a young girl suffering from Congenital Dislocation of the Patella.—Mr. JACKSON CLARKE discussed the case and Mr. COLLIER replied.

ÆSCULAPIAN SOCIETY.

Presidential Address.

A MEETING of this society was held on Oct. 7th, when the Presidential Address was delivered by Mr. D. H. GOODSALL, who took "Provincial Provident Dispensaries" as his subject. He said that at the present time the medical charities, certainly the medical charities of London, are grossly imposed upon. A large number of people receive gratuitous medical and surgical treatment which ought to be paid for. Where letters of recommendation are useful—and they do assist the patient at most medical charities—a common plan adopted by those who ought not to receive free medical aid is to get a letter from a subscriber through either a friend or a servant of the subscriber to the charity for which a letter of recommendation is required. The difficulty in preventing this form of fraud is well known and so far no reliable means for preventing it has been adopted, for many of these patients when questioned about their means conceal their true position. That provident dispensaries when well managed can do a

Digitized by Google

great deal towards removing the abuse of our medical charities and can also give the necessitous poor a much more thorough help in sickness than they are now receiving is shown by the results attained in seven provincial dispensaries which have been in operation for many years. The dispensaries are in the following towns—viz., Derby, Leamington, Leicester, Northampton, Reading, Tunbridge Wells, and Worcester. A provident dispensary has existed at Reading since 1802. The seven dispensaries show an average existence of upwards of 50 years and their total membership in 1897 was 101,455. As the total population of these towns amounts to 465,000, 21·7 per cent. of the population were members of provident dispensaries. The average payment per member per annum was 3*s.* 7½*d.* The highest payment (at Tunbridge Wells) was 4*s.* 11½*d.* and the lowest (at Reading) was 3*s.* A strict wage limit is in force in all these towns and rules exist by which a member whose position shall have become improved during his membership shall have his name removed from the books of the dispensary. The wage limit varies from £1 per week at Derby to 35*s.* at Tunbridge Wells. Without these dispensaries every one of the members would be eligible for treatment at the hospitals of the seven towns, and most certainly at any hospital in London—i.e., if the members wished to go to them. There is undoubtedly a strong feeling with some of the very poor that they would rather pay their medical man for his attendance than receive free medical relief, but with the majority of the working classes it is not so. Under the present arrangements in London a few of the poor pay a very little and the majority of the poor escape payment altogether. The hospital patients in the seven towns referred to numbered 56,346 out-patients and 10,602 in-patients during 1897, showing a percentage of 12·1 of out-patients and of 2·2 of in-patients. In comparison with those seven towns the following five towns may be taken where provident dispensaries are not stated to exist.

Town.	Population.	Hospital beds.	In-patients.	Proportion per cent. of in-patients to population.	Out-patients.	Proportion per cent. of out-patients to population.	Number of medical men.
Chatham	31,657	101	916	2·9	16,505	52·1	12
Hastings	52,223	78	604	1·15	2,665	5·1	?
Bath	51,844	327	3111	6	18,625	36	86
Bradford	216,361	531	3135	1·45	20,726	9·4	126
Birkenhead ...	99,857	170	1345	1·35	16,287	16·3	97

At Bradford the hospital staff paid 3052 home visits; this may mean that many patients having met with accidents were sent home and seen there instead of being admitted.

The above five towns give a total population of 441,942. The out-patients numbered 74,808, or 17 per cent. of the population. The in-patients numbered 9111, or 2 per cent. of the population. This comparison of towns with provident dispensaries as against towns without provident dispensaries shows that the out-patients are over 40 per cent. greater in the non-provident than they are in the provident towns. In the non-provident towns this increased percentage of out-patients did not contribute anything towards the cost of their treatment—i.e., the cost of drugs, &c., must have been paid by the charitable public. When compared with the seven provident towns they should clearly have contributed something towards this expense, and should have also paid the medical men who attended them. With reference to the benefit of the provident dispensaries to the poor the following advantages are given to them in the seven towns: (1) The right to apply at once for immediate medical attendance; (2) the right (in many of the towns) to consult the nearest medical officer in case of accident or sudden illness; (3) the right to choose their own medical officer when joining the dispensary; (4) the right to change the medical officer at stated times, and during an illness if the committee consent; (5) the feeling of security that in case of prolonged illness they will not incur a debt which they might find great difficulty in subsequently discharging; and (6) the encouragement of thrift and self-reliance. In reference to medical men the advantages of provident dispensaries are that (1) in accordance with the work they do for the working poor they are certain to receive some remuneration, the amount depending upon the time they devote to the work; (2) they are relieved from all trouble of supplying medicines to the poor patients; (3) they have no records to keep of the indebtedness of these patients; and (4) they have no trouble in collecting the amounts due from the patients. In the seven towns with provident dispensaries the total payments by members during 1897 amounted to £17,699 1*s.* 10*d.* The balance left after defraying expenses was £12,033 6*s.* 4*d.*, which was divided among the 76 medical officers of the provident dispensaries in those towns, giving an average of £158 6*s.* 8*d.* It may be fairly assumed that all the patients who belong to the provident dispensaries of those towns, representing 21·7 per cent. of their population, were really members of the working-classes.

CLINICAL SOCIETY OF MANCHESTER.

The Treatment of Summer Diarrhœa in Children.

A MEETING of this society was held on Oct. 18th, Dr. A. HILL GRIFFITH, President, being in the chair.

Dr. ASHBY opened a debate upon the Treatment of Summer Diarrhœa in Children. He said that the annual epidemic of summer diarrhœa with its death-roll of infant life—which has been exceptionally heavy this year—reminds us how ineffectual are our means for preventing as well as of treating this disease. Year after year with the advent of hot weather comes a visitation of acute gastro-intestinal disease which gives rise to a high mortality among infants during the acute stage and leaves many others in a permanently damaged condition. It is the universal experience that a close, hot atmosphere maintained during the whole twenty-four hours for days together is the indirect cause of the epidemic. It is well known that the heat wave supplies favourable conditions for the increased growth and virulence of various organisms, especially those which are liable to find their way into commercial cows' milk. It is tolerably certain that not one special bacillus but many are capable by their growth of forming toxins which are of a highly deleterious character. Having found entrance into the alimentary canal by means of milk or other food, the formation of toxins or toxalbumins quickly follows, which, being absorbed into the blood, give rise to fever, depression of the heart, suppression of urine, and drowsiness, and affect all the tissues of the body. Moreover, the bacteria in the alimentary canal may penetrate into the blood-vessels and give rise to inflammations in other organs, such as the lungs and meninges of the brain. Locally the toxalbumins are apt to give rise to an enteritis which chiefly affects the large bowel and lower end of the ileum, the reason doubtless being that in these parts the toxalbumins are longer in contact with the lining membrane of the bowel than they are in the upper part of the alimentary tract. Among the most important means for preventing these epidemics must be mentioned an improved condition of things as regards our milk-supply. A greater care of the health and cleanliness of the cows and byres, a rapid cooling of the milk to a temperature of 40° F., and maintenance of this temperature during the conveyance of the milk from the cow to the consumer must be reckoned amongst the most important measures of prophylaxis. The first indication for treatment is the evacuation of the contents of the stomach and alimentary canal. The vomiting which usually occurs is doubtless salutary and may be assisted by means of warm water if the infant or child will take it, or, still better, the stomach may be washed out. Stomach washing is urgently called for in cases with no vomiting and much collapse. Calomel is the best evacuant drug; if there is no vomiting it should be given in ½ gr. or 1 gr. doses and repeated once. If the vomiting is troublesome doses of from ⅛ gr. to ⅒ gr. should be given half-hourly. All milk must be stopped, and barley water, white of egg in sugar water, and chicken tea or whey given in small quantities at a time. Diluted brandy if there is any appearance of heart failure should be given. Very many drugs have been used, and recently drugs which are supposed to disinfect the alimentary canal have been much in vogue; that they are disappointing most will admit. Bismuth nitrate in large doses, from 5 to 15 gr. every two or three hours, is as useful as any. Opium

Digitized by Google

has fallen to some extent into disrepute in the treatment of infantile diarrhœa, and Dr. Ashby believes undeservedly so. The griping and colic caused by the enteritis can certainly be soothed by small doses of opiates and the excessive drain on the system checked. Enemas of starch and opium or ½ gr. of Dover's powder repeated every hour or two may be safely given within forty-eight hours of the onset of the attack to infants six months or a year old provided there is no marked drowsiness or contraction of the pupils. Washing out the large bowel by enemas of starch and boric acid by means of a soft indiarubber catheter attached to a ball syringe or funnel is certainly useful; from 20 to 30 oz. may be injected and allowed to escape by the side of the catheter. In this way the fæcal matter and toxins may be removed and the irritable bowel soothed.

Dr. W. E. FOTHERGILL stated that in hospital practice he had found all varieties of feeding-bottles unsatisfactory and had therefore discarded them entirely in favour of spoon-feeding.

Dr. J. WESTMORLAND, who had resided for two years in Southern California, referred to the fact that diarrhœa was not so rife in that country as it was here, although the temperature was much higher. He attributed this to the milk and fresh meat being cooled at once on ice and afterwards being constantly kept at a low temperature until required for use.

Dr. P. R. COOPER alluded to some bacteriological observations he had made on summer diarrhœa in rabbits, which disease he had noticed was coincident with an enormous increase in the number of "resident" bacteria in the intestine. He suggested that the summer diarrhœa of children was accompanied by an increased proliferation of the normally resident microbes, which at the same time became pathologically virulent. This would explain the occasional occurrence of this disease in breast-fed children, although admittedly the majority of cases were caused by fresh invasions of organisms introduced with fermenting and unsuitable food. He was opposed to the use of feeding-bottles. He had tried most of the so-called intestinal antiseptics with disappointing results, but had had better success with the use of turpentine enemas in certain cases.

Dr. J. PRICE WILLIAMS thought that little could be done to reduce the mortality from infantile diarrhœa unless the health authorities would issue early in the summer instructions to the public as to the precautions they should take against the disease and the importance of obtaining medical advice at the very outset of the attack.

Dr. WILKINSON (Oldham) considered that the temperature of the soil had much more to do with this disease than the temperature of the air. He preferred the boat-shaped bottle to spoon-feeding and thought that sterilisation of the milk was the best preventive. He recommended that in the very early stage of the disease nothing should be given for a few hours except sips of tepid water and that milk should be altogether avoided.

Dr. ARNOLD LEA had adopted in some cases of collapse subcutaneous injection of saline fluid under the skin of the abdomen or back. This had always caused marked improvement and had been the means of saving some cases which would otherwise have proved fatal, but unfortunately the good effects were in many cases only temporary.

Dr. DULBERG in certain advanced cases had had very good results from the use of small doses of opium in a little Parrish's food and from feeding with Mellin's food in very small quantities at a time.

LIVERPOOL MEDICAL INSTITUTION.

Exhibition of Cases.—Immunity after Excision of Malignant Disease. — Pneumonia. — Intussusception in Young Children.

A MEETING of this society was held on Oct. 20th, the President, Dr. MACFIE CAMPBELL, being in the chair.

Dr. CATON showed a man suffering from Elephantiasis of both legs and feet; the patient had never been abroad.

Dr. BARENDT read notes and showed a child, aged two and a half years, suffering from Xerodermia Pigmentosa. The disease affected the face, neck, and forearms. The skin elsewhere was healthy. Treatment by burnt amber ointment (2 dr. to 1 oz. of lard) had no effect. He proposed to apply the x rays.—Dr. LESLIE ROBERTS and Dr. G. STOPFORD TAYLOR spoke.

Mr. C. THURSTAN HOLLAND read notes and exhibited a patient, a boy ten years of age, who had suffered from Lupus which affected a large area of the left cheek. He had treated it by the x rays—eighteen exposures, each of 15 minutes' duration, extending over a period of two months. The ulcerated patch had quite healed. For five years previously the boy had been scarified and cauterised and treated in many other ways without any good result. The scar was supple and there was now no sign of breaking down three months after cessation of the treatment.—Dr. LESLIE ROBERTS alluded to risks of dermatitis from the use of x rays.—Dr. STOPFORD TAYLOR had treated two cases of deeply infiltrated lupus of the face without benefit by the x rays. In another case of lupus of the face with corneal ulcer an acute inflammation of the eye was set up. He congratulated Mr. Holland on the case shown.—Dr. CARTER, Dr. BARENDT, Dr. GIVEN, and the PRESIDENT having spoken, Mr. HOLLAND, in reply, thought the fear of dermatitis being caused by x rays much exaggerated. He had used the x rays in over 700 exposures and had never seen it.

Dr. NATHAN RAW showed a patient, a man, aged thirty-two years, whom he had trephined for Traumatic Epilepsy. The man fell, ten months ago, on his head, and after a long illness recovered and went to work. Seven weeks ago he commenced to have epileptic fits and was admitted to hospital unconscious. He had twenty-one fits in one day and became comatose. Trephining and removal of nearly the whole of the right frontal bone, which was irregularly depressed from fracture, was followed by cessation of the fits and in six weeks he was discharged.

Mr. F. T. PAUL read notes of Two Cases of Immunity after Excision of Malignant Disease. The first case was one of extensive epithelioma of the tongue, floor of the mouth, right tonsil and glands of the neck in a man, fifty-one years of age. An operation was performed in 1893 for its removal. Six weeks later the glands were removed. He made a rapid recovery and worked hard and lived sparingly until recently when an extension of the disease was found in the new floor of the mouth with glandular infection. This was removed. The second case was one of removal of a carcinomatous breast and axillary glands twelve years ago. There had been no recurrence.—Mr. MITCHELL BANKS observed that since no successful treatment had yet been found they were bound to go on improving the operative procedure. Early removal with a fair margin of apparently healthy tissue gave good results. He deprecated such proceedings as removal of the upper extremity in cancer of the breast and axilla and considered it discreditable to surgery when severe and incomplete operations were performed.—Dr. IMLACH said it had taken three years to answer a paper written by Dr. E. T. Davies against cancer surgery. These two patients, only one of whom was free from disease, were still living, and this was encouraging. But great surgeons, as Sir Benjamin Brodie and Sir James Paget, after a lifelong experience of cancer surgery always recanted from their early belief in it at the end of their career. — Dr. ALEXANDER and Mr. RUSHTON PARKER also spoke.

Dr. ABRAM read notes of three cases of Pneumonia. In the first case, that of a young athletic man, aged twenty-six years, gangrene of the lung supervened, followed by recovery. The second case occurred in a man, aged fifty-one years. Maniacal delirium was present. The administration of a drachm dose of tincture of digitalis, followed six hours later by a dose of two drachms, quietened him and he recovered. The third case ran a long course due to extension of the mischief to the upper lobe of the lung and the development of a pure pneumococcal empyema, which was opened. Dr. Abram held that opening such an empyema was sure to get rid of the fibrinous masses met with in these cases and favoured quick resolution.

Mr. R. W. MURRAY read a note on the Treatment of Intussusception in Young Children. He mentioned the high mortality in this affection, and after drawing attention to the uncertainty and dangers of rectal injections strongly advocated primary laparotomy.—Mr. HAWKINS-AMBLER had no idea that the results of laparotomy in this condition were so good as described. The chief dangers arose from delay in recommending operation and in advanced cases of attempting to do too much. He gave a case where enterotomy was performed on the ensheathing intestine and the gangrenous bowel removed through this opening.—Mr. PUZEY observed that there were cases where hydraulic pressure was obviously called for. He instanced a case in a child, aged five years, with an intussusception protruding from the anus, in which

Digitized by Google

hydraulic pressure was successful.—Dr. A. C. E. HARRIS strongly advocated operation and thought rapidity of performance of such operation of extreme importance.—The PRESIDENT, Dr. IMLACH, Dr. BARR, Mr. RUSHTON PARKER, and Dr. ARMSTRONG also spoke.

SHEFFIELD MEDICO-CHIRURGICAL SOCIETY.—At the opening meeting, held on Oct. 13th, the President, Dr. Alfred Robinson (Rotherham), introduced the subject of Vaccination by glancing at the figures presented to Parliament by the Royal Commission on Vaccination and which compelled the Government to take action. He pointed out the relation of infant vaccination and its neglect to the age incidence of small-pox. During the seven years 1848–54 of 1000 deaths from small-pox 677 occurred among children under five years of age, whilst in the subsequent groups of five years the proportional number steadily declined to 193 in the years 1885–89 and afterwards rose again to 283 per 1000 in the years 1890–94, concurrently with the decline in infant vaccination. So that it seemed impossible to avoid the connexion between the rapid increase of small-pox and vaccination default. Europe 100 years ago was decimated by the ravages of small-pox, the loss of life being estimated at 400,000 yearly. On the introduction of vaccination and revaccination the immunity was so astonishing that it seemed as if the disease had vanished from Europe. Indeed, in Germany, where vaccination and revaccination were insisted upon, it was almost unknown as an epidemic and was seldom found in any but frontier towns. It was from facts and figures such as these on which the Royal Commission made its recommendations, three out of four being embodied in the Bill, the only one omitted being the State payment of private practitioners for successful vaccination. The gains of the Bill were stated to be—(1) age limit extended from three to six months; (2) operation to be performed by the public vaccinator at the child's home if required; (3) the use of glycerinated calf-lymph; (4) the conscientious objector allowed his liberty; (5) an objector cannot be convicted more than twice; and (6) recalcitrants to be treated as first-class misdemeanants. Going on to the omissions of the Bill the President pointed out that no lists were prepared for public vaccinators after the age of four years; it laid no duty on school boards in connexion with children on entering school life; finally, when children reached the age of twelve years, at which time revaccination ought to be performed, when their parents were still less likely to object, the Bill made no provision for any action being taken as regards either vaccination or penalty or declaration of conscientious objection. The President regretted the indefiniteness of the term "conscientious objection" and expressed the hope that in any future Bill sanitary authorities would have charge of vaccinal administration and also that prosecutions should be conducted by public prosecutors. In conclusion, he pointed out that the Bill was an admitted compromise, though on the right lines. It had done something, on the one hand, to remove legitimate grievances and plausible objections raised to the practice of vaccination; whilst, on the other hand, it sought to provide facilities for vaccination which had never been enjoyed before. The line taken with regard to compulsion was again that of least resistance. At present about one-third of the children in England and Wales escaped vaccination, but with an amended Act in which the gravest objections were removed much of the opposition might die out. The Act was of a temporary character, it being understood that in its present form it was to remain law for five years only. The President's opinion was that the medical profession would not rest satisfied with the law as it stood; its ethical traditions had always been to protect every life against even that life's own ignorance and self-will. It disowned the selfish maxim, "Am I my brother's keeper?"

OXFORD MEDICAL SOCIETY.—The first meeting of the session was held on Oct. 21st in the Radcliffe Infirmary, Mr. H. P. Symonds (President) being in the chair. The minutes of the last meeting and the financial report were read by the secretary, Dr. Duigan, and were approved. The following is a list of the officers who were elected at the annual meeting in June:—President: Mr. H. P. Symonds. Vice-Presidents: Professor Gotch and Dr. Brooks. Secretary and Treasurer: Dr. Duigan. Council: Dr. Collier, Dr. Ritchie, Dr. Farmer, Dr. Ramsden, Dr. Elsmore and Surgeon-General Bradshaw, C.B.—Mr. Sankey read notes of a case of Apparent Rupture of an Ovarian Cyst and exhibited the patient. A single woman, aged sixty-five years, first noticed a swelling of the abdomen in June, 1897. In September, 1898, she had a fall and had severe pain in the abdomen after, and coming now under observation she was found to have an enormous distension of the abdomen (measuring about 50 in.); there was dulness in front, with fluctuation; the flanks were resonant. An ovarian cyst was diagnosed, but there was evidence rather of bruising than of rupture of the cyst. Four days after the accident the patient passed an unusual quantity of urine and the abdomen began to get smaller until it only measured, as at present, 36 in. in circumference.—A discussion followed, in which other cases of rupture of thin-walled parovarian cysts were mentioned, where absorption of the fluid by the peritoneum had occurred, and in one case this was associated with the passage of a large quantity of urine.—Dr. Collier showed a case of Sarcoma of the Sternum involving the ribs. The heart and lungs appeared to be healthy. The treatment by injection was discussed.—Dr. Roe exhibited a case presenting some features of Insular Sclerosis. A man, aged thirty-three years, noticed weakness and difficulty in walking eight years ago. His eyesight became affected five years ago, there being loss of vision in the centre of both visual fields. At this time he was a fairly heavy smoker. There was no history of syphilis or alcohol. The knee-jerks were exaggerated and there was ankle-clonus. There was no loss of sensation. His gait was at times ataxic. He was very loquacious, but speech was normal and there were no delusions.—Mr. Doyne, who had investigated his ocular symptoms, said there was central scotoma of both eyes but there were no peripheral scotomata. It differed from tobacco amblyopia. He regarded it as a case of insular sclerosis, such cases being sometimes indistinguishable from commencing general paralysis.—Mr. Symonds showed a case of Bronchocele where tracheotomy had to be performed during the removal of the gland. He also showed a case of Congenital Dislocation of both Hip-joints, comparing it with a case of extreme rachitic deformity of the femora.

SOCIETY OF ANÆSTHETISTS.—The sixth annual meeting of this society was held at 20, Hanover-square, W., on Oct. 20th, the President, Dr. Dudley Buxton, being in the chair. The reports of the council and treasurer described the condition of the society as flourishing. The following officers for the coming session were elected:—President: Dr. Dudley W. Buxton. Treasurer: Mr. G. Eastes. Members of Council: Mr. Edgar Willett, Mr. E. F. White, and Mr. Sydney Rumboll (Leeds). Secretaries: Dr. R. Turle Bakewell and Dr. E. H. Grant Morris. Auditors: Dr. R. Probyn-Williams and Dr. McCardie (Birmingham).—The President proposed votes of thanks to Mr. Joseph White, who retired from the post of treasurer on account of illness, and also to the ex-secretary, Mr. E. A. Starling, which were carried unanimously. At the conclusion of the formal business a dinner attended by the members and their guests afterwards took place at Limmer's Hotel, Conduit-street, under the chairmanship of the President, Dr. Dudley Buxton. After the usual loyal toasts Mr. Howard Marsh proposing the toast of the evening, "The Society of Anæsthetists." He said that the great improvements in modern surgery had been produced by the introduction of anæsthetics and by the labours of Lord Lister. Anæsthetists were perhaps specialists, but they must also be good physiologists and pathologists, and must have a good knowledge of clinical medicine, whilst many were admirable surgeons and often able to give valuable hints to the operator. Moreover, they seemed always amiable, always ready to help to their utmost and in a way which made surgeons very thankful. He was pleased to see several lady anæsthetists also present that evening.—The President, in replying for the society, said that anæsthetists were peculiar in that they had few if any opportunities of seeing each other at work. It was therefore of peculiar advantage to them to have a society such as the Society of Anæsthetists, which enabled them to tell one another their special methods, their difficulties, and their failures. These last were perhaps the most instructive. The society was extremely flourishing and had taken a step which he thought would greatly extend its benefits. He referred to the first publication of the Transactions of the society. In this way they had been able to focus their work and supply a ready means for referring to the valuable papers, discussions, &c., which had been given during the year. He referred to the accord between surgeon and anæsthetist which robbed the duties

Digitized by Google

of the anæsthetist of their grimmer side and aided him on the many occasions when he had, as it were, to dispute step by step with possible catastrophe.—Mr. George Eastes proposed the toast of "The Visitors," which was replied to by Professor Schäfer.—The health of the President was proposed by Dr. Silk and drunk with musical honours.—During the course of the evening Miss Cherry sang with much feeling, Mr. Schartau rendered some humorous songs, and Mr. Churcher recited and gave some amusing sketches.

CHELSEA CLINICAL SOCIETY.—A meeting of this society was held on Oct. 18th, Mr. J. Foster Palmer, President, being in the chair.—The Chairman having thanked the members of the society for electing him their first President, and having referred to the remarkable advances in modern surgery and the continued invasion by the surgeon and the specialist of the functions of the physician, which threatened to bring about the gradual extinction of the latter, proceeded to the subject of his inaugural address on "Certain Undefined Factors in the Spread of Disease." The factors referred to were (1) pathogenetic evolution; (2) abnormal objective receptivity; and (3) retrograde metamorphosis. Each of these factors was dealt with separately in its relation (1) to the history of former epidemics; (2) to clinical experience; and (3) to bacteriological research. The conclusions arrived at were: 1. That however tempting evolution may be as a pathological theory there is not in the present state of our knowledge any trustworthy evidence to show that it is in any sense a general law of nature among the pathogenic micro-organisms. 2. That receptivity is essentially an abnormal condition brought about either by some external insanitary influence or by some personal defect, either hereditary or acquired, and that an ideally healthy person is proof against the toxic effects of pathogenic microbes. 3. That decomposing animal and vegetable matter forms the best possible nidus for the growth and cultivation of the pathogenic bacteria, and that it is only the presence in the air of the products of retrograde metamorphosis which makes infection possible.—Dr. Morris, Dr. Ball, Dr. Gibbes, Mr. Nitch-Smith, Dr. Penny, and Dr. Vinrace also spoke, and a vote of thanks was given to the President for his address.—On behalf of Dr. Marsh, who was absent, the President, seconded by Dr. Penny, moved that a letter of condolence be sent to the family of the late Mr. Fallows, a member of the society who was lost on the Atlantic liner *Mohegan*. The motion was carried.—A resolution was also passed in reference to Dr. Cooper, the secretary, to whom the society owed so much, and who was then absent on his wedding tour. Seven new candidates were proposed for election as members.

GLASGOW MEDICO-CHIRURGICAL SOCIETY.—The second meeting of this society was held on Oct. 21st. Dr. W. K. Hunter showed: (1) A child with Hemiplegia associated with Diphtheritic Paralysis, the hemiplegia being apparently due to hæmorrhage; and (2) a well-marked case of *Maladie des Tics*.—Dr. James Carslaw showed a young woman with painful Swelling of the Limbs, presenting resemblances to erythromelalgia.—Dr. R. S. Thomson read a paper on an Infectious Disease occurring in Lascars, having relations to variola and varicella, but differing from both in certain points. This paper was published in THE LANCET of Oct. 22nd.

Reviews and Notices of Books.

Twentieth Century Practice: an International Encyclopædia of Modern Medical Science. By Leading Authorities of Europe and America. Edited by THOMAS L. STEDMAN, M.D. In 20 vols. Vol. XIV.: Infectious Diseases. London: Sampson Low, Marston, and Co. 1898. Pp. 602. Price 21*s.* cloth; 30*s.* leather.

THE issue of the volumes of this literary undertaking, which stands comparison with the famous Cyclopædia edited by von Ziemssen, proceeds with praiseworthy regularity. Its international character, too, is well sustained, for the present volume contains contributions from England, France, Germany, and Brazil, as well as from the United States. The first article is on Scarlet Fever and is by Dr. F. Forcheimer of Cincinnati. He reviews the different lines of research adopted to discover the contagium vivum of the disease, inclusive of the classical contribution made by Dr. Klein twelve years ago in the Hendon cow disease and the subsequent announcement by Dr. Edington of his discovery of a specific bacillus. Whilst compelled to admit that the evidence is inconclusive as to the specific identity of any microbe yet discovered, Dr. Forcheimer thinks that scarlet fever has an intimate connexion with streptococcic infection. The septic character of its more severe types may perhaps be explained on this ground. In regard to scarlatinal nephritis he makes it clear that it is directly related to the virus of the disease and that it is mainly a glomerulo-nephritis, as Klebs first pointed out. He considers, too, that clinically—especially the degree and frequency of dropsy—it has distinctive characteristics. The supervention of cardiac dilatation upon this form of nephritis is also emphasised, whilst mention is made of the occasional occurrence of peri- and endo-carditis in scarlet fever apart from the "rheumatism" to which the fever may lead. Puerperal and surgical scarlet fever are regarded as being sometimes due to infection by ordinary channels, at other times by inoculation, which may account for the different characters they may exhibit. The symptoms are discussed under the heads of, first, the Normal Form, and, second, Aberrant Forms, which comprise (*a*) rudimentary forms; (*b*) grave, excessively developed forms; and (*c*) complicated forms. Such a division seems cumbrous beside the more scientific classification adopted by Dr. Caiger in his article in Allbutt's System of Medicine of (1) simple, (2) septic, and (3) toxic. In the section on Treatment attention is drawn to the variable results obtained from the use of Marmorek's serum in the various septic complications, and in speaking of antipyretic measures the author says he has long abandoned the use of drugs, whilst the claims of hydro-therapeutics are fully recognised. Dr. Dawson Williams (London) contributes a very complete study of Measles. Commencing with statistics upon seasonal prevalence and age incidence, the subject of etiology is discussed in an impartial manner, the uncertain results of bacteriological research being noticed. The symptoms are detailed in turn, the characteristics of the rash, the type of fever, its duration, and the concomitant phenomena as ordinarily met with being first described. Dr. Williams then notes the several "departures from the usual course" which may take place, and there follows an excellent study of the complications of measles. The frequency of otitis as a complication is insisted upon and the share taken by measles in the production of deaf-mutism is specially noted. Nor must we omit to mention the account given of the nervous complications and in particular of the forms of disseminated myelitis and sclerosis which have indubitably been traced to the action of the virus of measles. The remarkable association of measles with tuberculosis is noted, whilst attention is called to the paroxysmal cough simulating pertussis which may arise from pressure on the trachea by enlarged bronchial glands. The subject of prophylaxis is dealt with at considerable length and the treatment of the disease and its complications is well described. Dr. Forcheimer writes the article on German Measles, in which he adduces convincing arguments as to its independent existence; Dr. Dillon Brown (New York) writes on Chicken-pox, one notable feature of his article being the description of the "gangrenous" forms, which he attributes to secondary septic infection. Dr. Dawson Williams gives a short account of Glandular Fever, the recognition of which is of comparatively modern date. The article upon Whooping-cough is the conjoint work of Dr. Joseph O'Dwyer (New York) and Dr. Nathaniel R. Martin (New York), and is perhaps most remarkable for the suggestion that the use of intubation may be of service to obviate the spasm of the glottis which is the characteristic

Digitized by Google

and most alarming feature of the affection. Dr. O'Dwyer speaks with authority on intubation, but we cannot find that he has carried out the practice in pertussis to any extent. He does, however, refer to the temporary use of intubation in three cases of whooping-cough complicated by diphtheria. He recommends employing rubber rather than metal tubes. Of course, any rational treatment of an affection which seems to be little influenced by drugs is to be welcomed; but unless it be admitted that the glottic spasm is the main feature of pertussis and that the cough will not continue should such spasm be mechanically prevented it does seem as if the laryngeal tube would with difficulty be retained in place. Dr. Jacobi (New York) writes in his usual clear and convincing style upon Cholera Infantum. The article is of especial value for its demonstration of the great share taken in this affection by improper feeding, and the author's remarks upon infantile diet, the sterilisation of milk, &c., will be welcome to all practitioners. The influence of hot weather is a factor in the disease which may in part be ascribed to its effect in lowering the resistance of the organism, in part to the readiness with which foods undergo change under such atmospheric conditions. Dr. Rumpf (Hamburg) contributes the articles upon Cholera Nostras and Asiatic Cholera. They are exhaustive and thoroughly scientific, and it is interesting to find their author concluding, at the close of a detailed discussion of its etiology, that the essential cause of Asiatic cholera is the comma bacillus discovered by Professor Koch. To the experienced hands of Sir Joseph Fayrer (London) has been assigned the subject of Dengue, whilst that of Beri-beri is contributed by Dr. de Arvedo Sodré (Rio de Janeiro), who has no doubts as to the infectious nature of this remarkable affection. Dr. Netter (Paris) writes upon Miliary Fever, which is still prevalent in some parts of France, and which he identifies with the English sweating sickness of mediæval times. Lastly, Major David Bruce of the Royal Army Medical Corps writes upon Malta Fever, a disease with which his name is so well associated.

The Living Organism: an Introduction to the Problems of Biology. By ALFRED EARL, M.A., late Scholar of Christ College, Cambridge; of the Inner Temple, Barrister-at-Law. London: Macmillan. 1898. Pp. 271. Price 6*s.*

IT is difficult to say whether this book is best adapted for a beginner or for the advanced student. It is intended for the former but the latter will read it with most profit. The beginner has too few facts in his possession to enable him to appreciate such general statements drawn from the consideration of numerous observations as are here frequently introduced and many paragraphs might be cited which require and imply wide and accurate knowledge on the part of the reader. On the other hand, the advanced student is generally disposed to continue to accumulate his facts rather than to spend his time in the consideration of abstract statements which afford him but little information.

The author commences by pointing out that the acquisition of knowledge is a gradual process beginning with simple perceptions and progressing within certain limits for each individual to the more complex, and requiring, in order that advances may be made in any subject, exact observation and the exercise of the intelligence. Biology, which not only, like chemistry, deals with the substance, but in addition with the form and identity, of certain objects, may be defined as a certain body of connected knowledge which is derived from the observation of living objects and from reflections based on that observation. The nature of life is considered and the difficulty of framing any definition which embraces all its manifestations is dwelt upon. As a general statement it may be said that any conception of physical life deals with ideas of form and change associated with differences of structure and function, and it is to facilitate the study of these that generalisations and divisions of our knowledge are made. The several systems of organs and their functions in man are then briefly described, as those of digestion, circulation, respiration, absorption, assimilation, and excretion, and these processes are compared with the corresponding ones in other animals and contrasted with those changes which are taking place in plants, and the conclusion is arrived at that both locomotion and feeding are acts which appear to have as one of their constituent parts *an element of choice, and it is this element of choice which is the most distinctive feature of vital change.* The author then proceeds to discuss the object and method of classifying objects and he indicates the importance of development in this respect. He shows that authority—or the formulated opinions founded on observations of careful and experienced observers—is of great assistance to investigators as representing the highest point of positive comprehension that has been attained, though it may still happen that many exact opinions are erroneous, their quality of exactness bringing them within the scope of inquiry and discussion—a statement which is more curtly expressed by Bacon when he observes that "truth is more easily educed from error than from confusion." Succeeding chapters deal with the material basis of life, the organism as a chemical aggregate and as a centre for the transformation of energy, and the meaning of sensation. Little, of course, can be given on these subjects that is certainly known, but the author's end will certainly have been attained if these difficulties have been clearly indicated and in some cases surmounted.

Idiopathic Ulcerative Colitis (Dysentery). By JAMES F. GEMMEL, M.B. Glasg. London: Baillière, Tindall, and Cox. 1898. 4to, pp. viii.–140. Price 12*s.* 6*d.*

THIS monograph is mainly the outcome of the author's experiences at the County Asylum, Lancaster. It goes to show that "dysentery," which at one time figured largely in the records of prisons, barracks, and asylums, still tends to appear and at times to prevail epidemically, and this notwithstanding the improvements which modern science has introduced into the construction and hygiene of such institutions. Although employing the term "idiopathic" Dr. Gemmel gives us good ground to believe that the disease is of microbic origin. With his colleague, Dr. Goodliffe, he has succeeded in isolating and cultivating a bacillus which has certain characters in common with the bacillus coli communis and the bacillus typhosus but which in other features can be distinguished from these forms. The gross anatomical lesions are hardly to be distinguished from those of tropical dysentery and the treatment of the affection follows on much the same lines. It is interesting, however, to find that quinine in large doses has been more efficacious in treatment than ipecacuanha, whilst the value of irrigation by large enemata is admitted. The perusal of this work confirms our opinion that much has yet to be learnt concerning the pathology of these forms of ulceration of the colon, and we are grateful to Dr. Gemmel for his valuable contribution to the subject. The book is admirably printed and well illustrated.

A Manual of Clinical Diagnosis by Means of Microscopic and Chemical Methods. By CHARLES E. SIMON, M.D., late Assistant Resident Physician, Johns Hopkins Hospital, Baltimore. Second edition. With 133 Illustrations in Wood and 14 Coloured Plates. London: Henry Kimpton. 1898. Pp. 563.

THE fact that a second edition of this work was called for in two years is sufficient evidence that the first met with the success which it deserved. Within the past

Digitized by Google

ten years a large number of books have appeared dealing with the value of the microscope and chemical analysis as aids to diagnosis and much advance has been made in this direction. Dr. Simon's volume has been brought well up to date. The parasitology and bacteriology of the blood, saliva, fæces, urine, and vaginal discharge have been almost entirely rewritten. New methods of chemical examination which have appeared since the publication of the first edition have been embodied in the work and some of the older and complicated ones have been omitted. We have found the different matters dealt with most completely described, the various chemical processes are clearly explained, and the microscopical technique will be clearly understood.

The chapter on Transudates and Exudates is an interesting one and contains information not usually found in text-books. Other chapters are also given on the Examination of Fluids which are usually neglected, although much useful knowledge might be obtained if they were more frequently submitted to chemical analysis and microscopic observation, such as the cerebro-spinal fluid, vaginal discharges, and the secretion of the mammary gland. The illustrations in a work of this kind are a very important feature, and in this matter Dr. Simon is certainly to be congratulated. A large number of them are borrowed and are of none the less value on that account, but many are original. Especially good are those depicting the parasites found in connexion with malarial fever; the methods of observing these organisms and the many varieties which are met with are very well given. The author has given this study a great deal of attention, for he thinks it "must be regarded as one of the most important in clinical medicine." Those who wish for detailed information on these parasites cannot do better than consult this work. The sections on the chemistry of the urine, too, contain a large number of useful hints, especially in the varieties of albuminous bodies which may be found. We can cordially recommend the book to our readers, both as a handbook to the clinical laboratory and also as a work of reference.

Les Cancers Epithéliaux: Histologie, Histogénèse, Etiologie, Applications Thérapeutiques. Par FABRE-DOMERGUE, Docteur ès Sciences, Chef de Laboratoire à la Faculté de Médecine de Paris. (*Epithelial Cancers: Histology, Histogenesis, Etiology, Treatment.* By FABRE-DOMERGUE, D.Sc.) Paris: Georges Carré et C. Naud. 1898. Pp. 462. Prix 30 fr.

THIS handsome volume, which, in point of paper, printing, and illustrations, leaves nothing to be desired, is devoted to the study of the cancers properly so-called, mainly from the structural and developmental standpoint. The author shows a profound familiarity with his subject and places his facts before the reader in a manner calculated to inspire confidence. Any contribution to more intimate knowledge of malignant disease is welcome, and if, as in this instance, the result is to show how much yet remains to be known such work cannot be without its value. Dr. Fabre-Domergue shows that he is entitled to speak with authority in microscopical anatomy and therefore the conclusion at which he arrives—after very full discussion—that the so-called coccidial parasites are only changes in the cell protoplasm must be held in respect. To those interested in this subject we recommend a careful study of the chapters which are devoted to this exposition. They abound in details and arguments which can be best appreciated by pathological histologists. The author does not deny the possibility of parasitism as a cause of cancer, but he endeavours to show that the case is not proven. It must not be supposed that the discussion of this question occupies the main part of the work. On the contrary, the development, relationships, and intimate structure of carcinoma—epithelial and glandular—may be said to form the basis of what constitutes a most interesting and valuable contribution to pathology.

LIBRARY TABLE.

Physiology, Experimental and Descriptive. By BUEL P. COLTON, Professor of Natural Science in the Illinois State Normal University. London: The Scientific Press. 1889. Pp. 423. Price 6*s.* — This, on the whole, well-written little book is suited for the upper classes in ordinary schools and contains the information in respect to the structure and functions of our bodies which should be possessed by every young man or woman entering life. The method adopted is to describe shortly but intelligibly the several organs, as the heart, lungs, kidneys, &c., but without going into very minute histological details. The function of each of these is described and in many instances illustrated by original and instructive diagrams. Directions are given that are appropriate for a teacher with a class before him and, finally, some simple experiments are appended which can be easily carried out either by the master himself or by the members of the class. The author has submitted his book to a considerable number of experts whose criticisms and suggestions he acknowledges in the preface to have been of much assistance to him, and as several of these gentlemen are inspectors of high schools, professors, and teachers, in the different States, the book may be considered as being issued with their approval and to represent the high-water mark of school education in America.

Phonographic Outlines of Medical Terms. Issued by the Society of Medical Phonographers. Second edition. 1898. London: Sir I. Pitman and Sons, Limited. Manchester: G. Pulman and Sons. Price 2*s.*—Although this is called a second edition it is practically a new book, for not only has the list of outlines and contractions been extended from some 2500 to about 3000, but a most useful list of similar words—i.e., words having the same phonographic outline and distinguishable only by vocalisation or position—has been added. To get the greatest amount of help from phonography it is necessary to habitually use the outlines which practice and experience have marked with approval and, for the most part, the outlines recommended in this list can be approved, but, as remarked in our notice of the first edition,[1] it is doubtful whether all experienced phonographers will endorse with approval all the forms shown. Upward and onward should generally be the guiding maxim in the choice of outlines, all other things being equal, and such niggling abominations as half-sized downward *h* and half-sized *t* for hydatid should be avoided. No student of phonography should neglect to study the list of similar outlines or to carefully peruse the deviations from the orthodox system which go so far to make phonography as here presented almost perfect for medical reporting.

Methods of Staining the Central Nervous System. By Dr. BERNHARD POLLACK. Translated from the second German edition by WILLIAM R. JACK, M.D., B.Sc. Glasg. Glasgow: F. Bauermeister. 1899 (*sic*). Pp. 132. Price 4*s.*—This is an exceedingly convenient reference book for those who are engaged in histological research, but it will be found too advanced for the beginner. The more widely-used methods, such as Nissl's, Marchi's, and Golgi's, are described in very full detail and there is an excellent account of Weigert's complicated stain for the neuroglia. An adequate account is also given of almost all the staining methods at present employed in neurological research. There are a good bibliography and a full index which will add to the value of the book.

JOURNALS AND REVIEWS.

The Journal of State Medicine. Vol. VI., No. 10. October, 1898. Baillière, Tindall, and Cox. Price 2*s.* — Much of this volume is taken up with the matters relative to Ireland

---

[1] THE LANCET, Feb. 1st, 1896, p. 299.

Digitized by Google

which were apparently brought before the members at the last meeting of the Institute of Public Health at Dublin. Mr. Cotton, M.I.C.E., furnishes an account of recent sanitary legislation in Ireland, and Dr. J. W. Moore a very readable paper on Ireland: its Capital and Scenery. Mr. Richard Kelly discusses the existing sanitary law and its possibilities, and the leading articles have reference amongst other subjects to typhoid fever in Belfast and to the East London water famine. We note that the forthcoming Harben lectures are to be delivered by Sir Richard Thorne.

The Journal of Anatomy and Physiology. Conducted by Professor Sir WILLIAM TURNER, Professor D. J. CUNNINGHAM, Professor A. MACALISTER, and Professor J. G. M'KENDRICK. Vol. XXXIII., Part. 1. October, 1898.—The contents of this part are: 1. The Significance of Anatomical Variations, by D. J. Cunningham, F.R.S. 2. A Study of the Arrangement of the Muscular Fibres at the Upper End of the Œsophagus, by A. Birmingham M.D.R.U.I., of Dublin. 3. The Arrangement of the Muscular Fibres of the Stomach, by A. Birmingham, M.D.R.U.I., of Dublin. 4. The Marsupial Larynx, by Johnson Symington, M.D. Edin., of Belfast. 5. An Interesting Case of Connexion between the Lungs and Systemic Circulatory System and of an Abnormal Hepatic Blood-supply in a Frog, by George P. Mudge, A.R.C.S. Lond. 6. A Case of Uterus Masculinus—Tubular Hermaphroditismus—in a Male, with Sarcomatous Enlargement of an Undescended Testicle, by A. Primrose, M.B. Edin., of Toronto, with a Plate. 7. A New Dissection, showing the Internal Gross Anatomy of the Hippocampus Major, by J. G. M'Carthy, M.D., of Montreal. 8. Note on a Fœtus of Gorilla Savagei, by W. L. H. Duckworth, M.A., with illustrations. 9. The Action of Certain Drugs and Mineral Waters on the Secretion and Composition of Human Bile, by William Bain, M.D. Durh. 10. The Peripheral Distribution of the Cranial Nerves of Ammocœtes, by R. Alcock, student of Newnham College, Cambridge, with a plate. 11. On the Origin of Vertebrates Deduced from the Study of Ammocœtes, by Walter H. Gaskell, M.D. Cantab., F.R.S., with two plates. The last article is the eighth report of the Committee of Collective Investigation of the Anatomical Society of Great Britain and Ireland for the year 1897-98.

Archives de Physiologie. Cinqième série. Tome x., No. 4. Paris: Masson et Cie. Octobre, 1898.—The articles contained in this part are the following:—1. Development of the Guinea-pig, by Charles Livon and H. Alezais. 2. Resistance of the Human Body in the Period of the Variable State of the Galvanic Current, by Dr. Dubois of Berne. 3. On the Existence in Mammals of an Oxydase-Globulin with an account of its Characters and Properties, by MM. J. E. Abelous and G. Biarnès of Toulouse. 4. On the Action of some Antiseptics on Soluble Ferments, by M. A. Treyer of Fribourg, Switzerland. 5. Analysis of the Thermic Phenomena which prepare, accompany, and follow Death by Refrigeration, by M. J. Lefèvre. 6. The Denitrifying Power of the Bacillus of Eberth, by MM. Hugouneng and M. Doyon. 7. Transmission of Toxins from the Fœtus to the Mother, by M. A. Charrin. 8. Researches on the Physiology of the Optic Thalamus, by MM. J. Sellier and H. Verger of Bordeaux. 9. Changes in the Nervous System Consequent on Burns, by Dr. Carlo Parascandolo of Naples, with a plate. 10. A Case of Tumour of the Pons with Degeneration of the Band of Reil, by M. E. Long. 11. Thermogenesis in Tetanus, by MM. D'Arsonval and Charrin. 12. Influence of the Thyroid Juice on Muscular Energy and Resistance to Fatigue, by M. A. Mossé of Toulouse. 13. Sources of Animal Heat, by M. F. Laulanié. 14. The Relation between the Size of the Body and the Development of the Encephalon, by MM. Dhéré and Louis Lapicque, with a plate. 15. Contribution to the Physiology and Pathology of the Labyrinth in Man, by Dr. Max. Egger. 16. The Application of the Radiograph to the Determination of Distances by Means of the Superposition of Two Stereoscopic Couples, by MM. T. Marie and H. Ribaut. 17. On Lipase, by M. M. Hanriot.

Dublin Journal of Medical Science.—The original communications are on the Duties of the Community with regard to Tuberculosis, by Dr. Joseph O'Carroll, and on Ireland, its Capital and Scenery, by Dr. J. W. Moore. There is a long article on Medical Education and Examinations in Ireland.

Scottish Medical and Surgical Journal.—The principal paper is one by Dr. William Russell, the editor, on the differentiation of cardiac murmurs. An entertaining article headed "As Others See Us" consists of a translation of the description of the recent meeting of the British Medical Association published in the *Deutsche Medicinische Woohenschrift.* A section on Medical Education in Scotland will be found useful by students.

Caledonian Medical Journal.—The principal feature is an address on Some Highland Doctors of the Past, delivered by Dr. Alexander Macdonald, President of the Caledonian Medical Society, at the eighteenth annual meeting of the society in Edinburgh last July. At the annual dinner held the same evening the menu and toast list, both of which were of some length and have been reproduced in the *Journal,* were entirely in Gaelic; "cofi," which comes last of all in the menu, is the only word intelligible to the ordinary reader.

Edinburgh Medical Journal.—Dr. Andrew Davidson discusses the Malaria Problem in the Light of Epidemiology, pointing out that epidemics of malaria connected with soil disturbance, the prevalence of the disease in extremely cold regions of Russia, and some other malarial conditions, have not hitherto found an explanation in accordance with the mosquito theory of transmission. Mr. Adams Frost describes the Operative Treatment of High Myopia, a method resuscitated by Fukula in 1889. Mr. Frost considers that the operation is of great benefit to myopes of not less than 15 D., enabling them to go about without glasses and, as a rule, giving them better vision than they formerly had with glasses. The treatment usually extends over a period of three months. Mr. Frost needles the lens freely at the first sitting. Dr. James Mackenzie (Burnley) has a very interesting paper, illustrated with sphygmograms, on the Alleged Retardation of the Pulse in Aortic Regurgitation. In place of the apparatus with a large revolving cylinder he used a much more convenient arrangement in which a tambour is combined with a Dudgeon's or von Jacquet's sphygmograph. His observations showed that there is no more retardation of the pulse in aortic regurgitation than there is in health. There is an Appendix of 36 pages on Medical Education in the United Kingdom and the Principal Public Medical Services.

The *Phonographic Record* for October contains a short but useful contribution by Sir William Gowers, suggested by a case of wrist-drop in which no blue line on the gums could be seen by the naked eye. With a 3-in. lens, however, a complete but narrow line was seen on the lower gum, whilst the points of gum between the teeth presented in many instances a decided black mark. A paper by Dr. Benson Cooke on the Palliative Treatment of Chronic Disease of the Uterine Appendages, Notes on a Case of Anomalous Convulsions and Pyrexia following Influenza by Dr. F. H. Spooner, an Account of the Post-mortem Examination of King George the Second, which was noticed in THE LANCET of Oct. 15th, and Notes of the Post-mortem Appearances in a case of Gunshot Wound of the Head complete the number.

The Student.—This magazine, published by the Students' Representative Council, Edinburgh University, contains a portrait of Dr. Robert Muir, recently appointed Professor of Pathology at St. Andrews University. A short account of his past appointments and his scientific work is also given.

Analytical Commission
ON
SHERRY:
ITS PRODUCTION, COMPOSITION, AND CHARACTER.

Introduction.

BY an obviously easy transition the "vino de Jerez"[1] became in the English language shortly *sherry*. Some hold that the derivation of Xeres, or, as it is now more commonly spelt Jerez, is from the Greek word Ξηρος, dry, and we have the words "seck," "sac," and in French "sec" applied to a dry wine, or a wine free from sweetness. Strictly speaking, therefore, sherry should mean Jerez wine and undoubtedly Jerez is the home of sherry. But "Manzanilla," a wine which is produced close by at San Lucar, to the west of Jerez, and "Montilla," a wine produced at Montilla, a town south of Cordova, are famous wines which come under the same category. Sherry, again, in the British Pharmacopœia is known as "vinum Xericum," and it is the only wine enjoined in the preparation of the wines of the Pharmacopœia except two—viz., vinum ferri citratis and vinum quininæ, which were made with orange wine. Thus sherry is directed to be used in the preparation of vinum aloes, vinum antimoniale, vinum colchici, vinum ferri (iron wire dissolved in sherry), vinum ipecacuanhæ, vinum opii, and vinum rhei. Sherry was originally employed for this purpose, doubtless to render the drugs indicated less objectionable to the taste and partly because it proved to be a good solvent of active principles and is in itself distinctly tonic in character. In the British Pharmacopœia of 1824 it is interesting to note that diluted spirit was substituted for wine without altering the name of the preparation, but the use of sherry was restored in 1836. We shall point out later why probably it was found that diluted spirit could not be substituted for sherry in the way which had been proposed. This is an interesting point in connexion with the chemical composition of sherry which, as we shall see, distinguishes it from most other wines, and in which some explanation may be found of the advantage experienced in practice of employing sherry as a menstruum. In the Pharmacopœia the only test described is that for salicylic acid, the recourse to which is exceedingly improbable, since, as is well known, sherry possesses remarkable keeping powers, due in part to its alcoholic strength and in part to its richness in antiseptic aromatics.

In defining sherry we may very properly call it a wine which is peculiar to Spain and essentially Spanish. There is no genuine wine like it produced in other countries. Of course, as with all good and genuine things, there is the counterpart in fictitious substances and there is undoubtedly much stuff sold in England as sherry which was more likely produced in Hamburg or in any other place than Spain but of which not a single drop ever found sustenance on the soil of Spain or flourished under the remarkable influences of the Andalusian sun. With these imitations we do not propose to deal, but having the real significance and meaning of the word "sherry" in mind it is clearly a fraud to pass off such decoctions as Jerez wine. It is akin to calling a spirit Cognac which is produced in the colonies or elsewhere. In referring to sherry, therefore, we must be taken to mean "vino de Jerez" or the well-known white wine produced in the province of Andalusia in Spain. There is no soil or similarly favoured environment other than that of the province mentioned which can produce wine of the peculiar character of sherry. The vines of Jerez, were they transplanted further afield or to other countries, would produce grapes which would fail to yield the same character of wine; they would miss the peculiar climatic conditions which give rise to a peculiar wine. Moreover, the great life process of fermentation is profoundly modified by external conditions; and the external conditions—soil, sun, and air, &c.—in the vineyards at Jerez and the adjacent districts produce sherry and sherry alone.

[1] Pronounced "herreth," the "her" as in herring.

The Production of Sherry.

By far the greatest quantity of sherry is produced at the sherry centre of the world, Jerez de la Frontèra. Chemistry and biology have not been brought to bear upon the production of sherry to any extent, and when the application of scientific principles has been tried the result has invariably spelt failure; but, doubtless, as the biology of the organisms concerned in the fructification of wine is better understood there will be greater certainty of the success of a vintage. Indeed, the conversion of the juice of the Jerez grape into sherry is the simplest possible process; it is essentially and purely a natural operation, and the grower is content to be an onlooker of this natural process with little power to influence its progress either for bad or good. Specific characters are, however, gradually developed by different butts of wine, or a wine may lack certain characters, and then the skill of the sherry grower comes into evidence. He cultivates the character he requires by inoculating a wine, as it were, with the properties of one of established excellence. Without going into minutiæ this is the so-called "solera" system. The solera wine, so to speak, is the breeding ground or mother liquor, on which young immature wines are placed to develop delicacy, refined taste, and good character. The "solera" is drawn upon again and again for blending and the quantity so abstracted is made up by the addition of a wine which in its turn requires this wholesome infection. Thus by a very interesting and beautiful method of culture depending upon the inherent properties of the fermented juice itself are the aroma, bouquet, and fragrance which are so marked a characteristic of sherry handed down from generation to generation of vintages, and the palatable and peculiar flavours of a sherry may happen to have descended from a wine perhaps three centuries or even a greater number of years old.

There are several types of sherries according to the different characters developed. These are known by several distinguishing terms comprehending the characters and specific qualities of the wine from one end to the other of a scale ranging from delicate and light wines to rich, generous, and dark-coloured wines. Broadly, however, sherry may be divided into two classes—the so-called "fino," a light-coloured, pale, delicate, light wine of the Amontillado or Manzanilla type, and the so-called "oloroso," a full-bodied, highly-developed brown wine. Intermediate in character—that is, between the "fino" and "oloroso" type—may be mentioned the wine classed as "palo cortado." All classes are produced in the several districts, but the wine of each district has its own peculiar characters. San Lucar, close by Cadiz, is famous for its delicate light wine (of the "fino" type), "Manzanilla," which is said to possess a faint flavour of camomile flowers, and in Montilla a particularly fine wine is produced presenting a most delicate bouquet and taste, sherries resembling Montilla wine but produced in Jerez being known as "amontillado"—that is, *à la Montilla*.

The Sherry Bodega.

The bodega is the sherry nursery. In reality it is an overground cellar and usually consists of a very large, lofty, and capacious building containing hundreds, and often thousands, of butts of wine in different stages of development. The interior of the building is kept as cool as possible and away from the influences of the sun, while the arrangements are such that a current of cool air is constantly passing through and ventilation is thus efficiently secured. It is here the tasting of wines goes on from day to day and changes are made according to the resulting observations. It is here the skill of the grower is chiefly centred and his delicate sense of smell and taste

Digitized by Google

is constantly employed in order to note what qualities his wines may be developing. Sherry, unlike most other wines, may be stored in butts freely open to the air; the wine improves rather than deteriorates under these conditions and becomes more "made," as it is said—that is, advanced in the direction of developing bouquet and delicate flavour. With the light delicate wine known as "fino" a "flor" or microscopic plant (mycoderma vini) develops on the surface which is highly regarded as the agent concerned in contributing excellent characters to this class of wine. Obviously such a wine cannot be bottled till the "flor" has ceased to grow, as otherwise an unfinished wine with murky appearance would be the result. The bodegas contain wines of every description and type and almost of every age, varying from a hundred years' to the last year's vintage. Sherry is pre-eminently a wine which improves with age and to this age there is no limit, the changes going on being chiefly in the direction of etherification and concentration of "vinosity." The bodegas and all premises connected with the production of sherry are quite open to the inspection of the interested visitor, and it may be added that practically three-fourths of the industry are carried on by English people.

The Nature of the Soil upon which the Sherry Grape Grows.

The Jerez vineyards are situated within a few miles to the north-west of the town itself on a series of undulations stretching right away towards San Lucar, which is on the coast just a little to the north of Cadiz, whence all the sherry produced is shipped to England and elsewhere. The soil is of a porous character, light, and of a greyish colour. Its approximate composition, according to an analysis made in THE LANCET Laboratory, is as follows:—

Analysis of Soil.

	Per cent.
Calcium carbonate	29·12
Oxide of iron, &c.	4·08
Sand, &c....	45·80
Soluble salts	0·50
Moisture	16·70
Loss on ignition	3·80
	100·00

Practically, therefore, a third part of the soil consists of carbonate of lime, an observation of some importance to which we shall have occasion to refer. The vines present the appearance after vintage of a group of gnarled stumps of an average of two feet in height. The grape is small and white. Vintage time is a harvest scene which is one of the most impressive spectacles in Spain.

The Sherry Wine-press.

The grapes are collected and placed in large panniers on the backs of mules and conveyed to the press-house. There are in some instances press-houses situated on the vineyards, but more often the grapes are pressed on premises connected with the bodegas in the town, and the string of mules so laden at harvest time on their way to the bodegas is a very picturesque sight. The "lagar," or press, is of primitive construction and identical still with the presses described in ancient history. It consists simply of a wooden trough about ten feet square provided in the centre with a screw press, which is used after the treading by foot power is done to express the final juice from the crushed mass. Rather less than a ton of grapes—or to be more accurate 1800 lb. (812 kilogrammes)—serves for one pressing. Men clad in light clothing and provided with a kind of wooden clog with nails on the soles and heels, pointing in a slanting direction, then proceed to tread the grapes in a perfectly methodical manner, proceeding row by row, each row being of the width of the pressing clog or boot. It is said that the average weight of a man is just sufficient to press out the juice without injuring the skins or branches, the bitter substances in which, if expressed, would give an objectionable character to the wine. It cannot be supposed, however, that modern ingenuity could not contrive a mechanical means of pressing the grapes to comply with these requirements and thus meet an objection which might be raised to a method and custom of which we read in the most ancient of ancient history. After the grapes have been trodden over for the first time, that is to say, partly crushed and bruised, a measured quantity of sulphate of lime ("yeso") is sprinkled over the sticky mass. The sulphate of lime employed is a pure native earth occurring in large quantities in the neighbourhood of Jerez. It is first burnt. Its analysis made in THE LANCET Laboratory is as follows:—

Analysis of Sulphate of Lime ("Yeso").

	Per cent.
Insoluble matters	2·30
Calcium sulphate	83·57
Calcium carbonate	4·57
Potassium sulphate	1·48
Moisture, &c.	8·08
Total	100·00

"Yeso" consists practically therefore of sulphate of lime with a small proportion of carbonate of lime; it is commonly added in the proportion of a little over a kilogramme (1140 grammes, or 2½ lb.) to a load of grapes weighing nearly a ton (1800 lb., or 812 kilogrammes). The grapes having been thus trodden several times the residue is swept up around the screw (branches first being picked out and thrown away) and bound up in a heap with strips of woven esparto grass and the press screwed down. This proceeding expresses more juice, which trickles away and joins the bulk previously expressed in a butt placed to receive it. The average yield of liquor or juice is 110 gallons, or 500 litres (i.e., about the capacity of a butt) per 1800 lb., or 812 kilogrammes, of grapes crushed. The butt is then placed in a convenient place and the juice is soon in an active state of fermentation, the temperature rising considerably. The fermentation subsides in about three weeks, when the wine immediately begins to clear. After a time the wine is "racked" or drawn off the lees or slimes and placed in other butts. In this condition it is known as "mosto." This is in reality young wine, and from this stage its progress is watched with the greatest care. How it will turn out nobody can tell. Time alone decides. It may develop into a "fino," a delicate light wine, breeding a "flor" and flowery bouquet and taste, or it may go into a highly vinous liquid developing the vigorous "oloroso" character, or it may become diseased, developing objectionable fungus, and go into vinegar or remain a vinous liquid of indifferent character. The sherry-grower would like to be able to control it at this point so as to get a result he would desire, but he is entirely in the hands of nature's caprices, preferring to wait and abide the result rather than resort to artificial correctives.

The Part Played by Sulphate of Lime.

The addition to the crushed grapes of a definite quantity of sulphate of lime has given rise in recent years to considerable discussion as to the advisability or even legitimacy of the proceeding. This recourse at any rate has existed as long as sherry has been known and this must have been from time immemorial, since Pliny, for example, says that it is an ancient African system.[2] Again, Shakespeare puts into the mouth of Falstaff the words, "There's lime in this sack." In modern days the process has become known as "plastering" from the fact that plaster-of-Paris consists principally of sulphate of lime or burnt gypsum. "Yeso" the Spaniards call it. It is interesting to surmise the origin of this very ancient custom. That it had some intelligent basis admits of no doubt. Some think that it had its origin in the fact being noticed that when the grape juice was fermented in alabaster vessels or in marble tanks the wine was better, it clarified quicker, and developed character more satisfactorily. Others regard the addition of sulphate of lime as convenient from a mechanical point of view during the pressing; it was necessary when the grapes were wetter than usual in order to bind the residuary mass together. We do not incline to this view.

According to many experiments which we have made we are disposed to think that the following is the correct explanation. It has at all events a very reasonable basis. The soil upon which the sherry grapes are grown consists, as a reference to the above analysis will show, of nearly one-third part of calcium carbonate or chalk, so that if the soil upon which the grapes actually grow were substituted for the sulphate of lime a similar, though it must be admitted not precisely similar, result would be effected. The result at any rate would be the same in regard to clarification and probably also in regard to development of character in the wine, provided the carbonate of lime in the soil or the soil itself were not in large excess. It is conceivable, therefore,

[2] Pliny: Natural History, Book xiv., p. 19.

Digitized by Google

that centuries and centuries ago it was observed that when a greater quantity than usual of soil was adhering to the grapes a better and more satisfactory "mosto" and wine were produced owing to the lime salts. It is not difficult to imagine that in some seasons the quantity of soil blown upon the grapes by the wind and fixed there by the stickiness of the fruit would be increased. This observation being remarked it was but an easy step to resort to what appeared to be a better, as it was a purer and whiter, soil for the purpose. And close by the vineyards occurs "yeso," a white earth containing for its principal ingredients sulphate and carbonate of lime, and this it seems probable was dusted over the grapes to imitate an action which frequently took place naturally. Whatever may be the explanation of the custom of dusting the grapes with sulphate of lime one thing seems clear, and that is that without exception every experienced sherry-grower is positive in stating that if this custom be omitted the result is a wine devoid of those special characteristics which distinguish sherry from other wines. We shall see presently how this experience of the sherry-grower is supported by the evidence gained on a careful analytical examination of wines produced both with and without the previous addition of sulphate of lime.

The addition of sulphate of lime effects one important change. It reacts with the tartrates or malates of potassium in the grape and yields in the resulting wine sulphate of potassium largely, but not entirely, in the place of these salts. Our own experiments show conclusively, we think, that the result may be represented in the following equation:—

$$2KHC_4H_4O_6 + CaSO_4 = K_2SO_4 + CaC_4H_4O_6 + H_2C_4H_4O_6.$$

The result of adding sulphate of lime, therefore, is to convert part of the potassium acid tartrate ($KHC_4H_4O_6$) into potassium sulphate (K_2SO_4), insoluble tartrate of lime ($CaC_4H_4O_6$) separating and going down with the lees, effecting rapid clarification (and as we shall presently show an important degree of fining), and leaving a large proportion of the original tartrate in the clear wine as free tartaric acid. The change will be understood more clearly if we consider first the composition of the lees or slime obtained in fermented grape juice ("mosto") previously treated with sulphate of lime and compare this with the composition of the slimes or lees deposited in "mosto" untreated with sulphate of lime. The analyses of the two deposits are as follows and the results are placed side by side for the purpose of admitting of ready comparison.

Analysis of Lees from (1) "Mosto" with Sulphate of Lime, and (2) "Mosto" without Sulphate of Lime.

There are some interesting and important differences here which after all are just what might have been anticipated, but so far as we are aware the comparative analyses of lees from treated and untreated wines have not hitherto been put on record. The differences in composition of the two lees bring out at once the advantage of the treatment, at any rate from the sherry-growers' point of view. We will consider the results from other points of view presently. The lees of wine which have been treated previously with sulphate of lime contain a greater proportion of organic matters than the lees of a wine not so treated, consisting of just those matters, such as albuminous bodies, which are likely if retained in the wine to make it susceptible to objectionable changes and deterioration. Again, tartrate of lime in lees of previously treated wine occurs largely, but not entirely, in the place of acid tartrate of potassium in the lees of untreated wine, but it will be observed that in the latter tartrate of lime is also an important constituent. The lees of treated wine further contain an increased proportion of free acid.

With these important differences fresh in the memory in regard to the composition of the lees of wine previously treated and untreated with sulphate of lime we may next in order show the differences in composition between the same wines racked off the lees—i.e., the clear young wines decanted from the deposits, the interesting difference in the composition of which we have just considered.

It will be seen that in these important results we have complete confirmation of the view expressed in the equation above; that the changes induced by the addition of sulphate of lime are the formation of sulphate of potassium in the wine, the separation in the lees of tartrate of lime, and the production of free tartaric acid. Thus the potassium acid tartrate in the untreated wine amounts to 0·28 per cent., whereas in the treated wine it is only 0·093 per cent., just one-third the quantity. It is important to note, however, that not all the acid tartrate of potassium has been removed. The quantity of potassium acid tartrate reduced is in proportion to the increase of free tartaric acid. Further, while the untreated wine contains 0·085 per cent. of potassium sulphate the treated wine contains 0·34 per cent., or just four times as much.

The two young wines (or "mosto") were produced side by side at the same time, they were racked at the same time, and the deposits or lees were collected at the same time. The deposit in the butt of the treated wine was considerably bulkier than that from the untreated wine.

The Effect of Sulphate of Lime on the Development of Ethers.

There is another point of considerable interest brought out in this analytical contrast and that is in regard to the ethers. The fixed ethers may be looked upon as contributing the peculiar flavour of wine and the volatile ethers the aroma. The type of the former is ethyl tartrate and of the latter ethyl acetate. Now although these wines were produced from grapes of the same vintage, were crushed, fermented, and racked at the same time and were of precisely the same age—though that was only a few months—yet there is a great and important difference in the amount of ethers. In the wine treated with sulphate of lime they are more than double in amount that of the wine not so treated. The explanation, we think, is not far to seek.

As already pointed out one effect of treating grape juice with sulphate of lime is to liberate free tartaric acid in the wine. In other words, the fixed acids of treated sherry are largely in a free state while in untreated sherry they occur in the form of the acid salt of potassium. In the former case alcohol being in the presence of free organic acid would, it may fairly be assumed, readily combine with the acid to form ethyl tartrate or other ethers of wine. In a word, the treatment with sulphate of lime stimulates etherification.

Two very simple experiments confirm this view. Five grammes of acid tartrate of potassium were repeatedly shaken up with 100 cubic centimetres of distilled water and the acidity of the clear solution was measured. Next, a precisely similar liquid was prepared, but this time a little sulphate of lime was added. The acidity was found to have increased by over 50 per cent. Part of the insoluble acid tartrate of potassium had been converted into tartrate of lime and free tartaric acid, and the latter being more soluble went into solution and increased the acidity accordingly. Further, when an excess of acid tartrate of potassium was shaken up with alcohol of the same strength as sherry and allowed to remain for some time, and the same process repeated, but with free tartaric acid instead of acid tartrate

Digitized by Google

of potassium, the amount of ethers when estimated in the latter at the end of the experiment was found to be nearly three times as much as in the former. The fact, again, of sherry containing free tartaric acid in place of the acid potassium salt explains the adoption of sherry in the Pharmacopœia and the probable reason why diluted alcohol was not found an efficient substitute for sherry for this purpose. As is well known tartaric acid is an excellent solvent of the active principles of drugs and as we have already pointed out sherry is used in conjunction with several drugs of the Pharmacopœia. Sherry, again, is for the same reason a solvent of iron, an organic salt of iron being formed.

Further, the fact that tartaric acid occurs in sherry largely in the place of the acid potassium salt by reason of the sulphate of lime treatment affords a very probable explanation of the fact that sherry excels all other wines in regard to etherial contents and possibly also the beneficial influences gained by storing whisky in sherry casks may have some connexion with the same fact. It explains also the stimulating and well-known tonic power of sherry compared with other wines, for as we shall see presently the ethers in old sherry amount to a very high proportion never attained by other wine, and this suggests an explanation of the extraordinary stimulating powers of old sherry which it is said is not possessed to the same extent even by real old Cognac. This stimulus which the changes effected by treatment with sulphate of lime give to the formation of ethers is of great interest in regard to what every sherry-grower maintains—namely, that without such treatment a wine of good, delicate, and generous character cannot be produced. The sherry-grower judges and values his wines by smell and taste and these senses are cultivated to a remarkable degree of refinement which enable him to anticipate the fate of a wine for good or for worse. In putting wine through these simple tests is he not making in reality an estimate of the volatile and fixed ethers, the former by smell and the latter by taste? In that case his judgment is completely and conspicuously confirmed by minute analyses which show that sherry previously treated with a small quantity of sulphate of lime contains and develops a more marked etherial character than sherry not so treated. By experience he has learned this difference and analysis shows his experience to be correct. Analytical and experimental chemistry would appear here to offer some explanation for the time-honoured adoption and the continuation of a process which has been in practice for probably more than a thousand years.

Sulphate of Potassium in Sherry.

We have next to consider the question and significance of the occurrence of potassium sulphate in the wine in the amount which our analyses of several types of sherries show. At the outset it should be pointed out that sulphate of potassium is not a foreign constituent of the grape or of the wine produced without any intermediate treatment with sulphate of lime at all. Further, grapes contain a definite quantity of calcium salts. These constituents are of course extracted from the soil and it follows that the soil must contain them. The particular soil which we examined did not appear to contain any important quantity of sulphates, but as a rule these salts are common constituents. In all the published analyses of grapes we find sulphate of potassium recorded as a constituent of the mineral matter; hence the soil must have contained this salt or its elements. These points are further developed in an analysis made in THE LANCET Laboratory of the Palomino grapes taken from the Jerez vineyards.

Analysis of Grapes.

	Per cent.
Water	74·05
Organic matter	24·94
Mineral salts	1·01
Total	100·00

Percentage Composition of Mineral Salts of Grapes.

	Per cent.
Calcium and magnesium salts (carb. sulph. phosph.)	46·30
Potassium sulphate	10·70
,, carbonate	31·78
,, phosphate	11·22
Total	100·00

Thus a tenth part of the mineral matter of the grape is potassium sulphate, and lime salts including the sulphate occur in large proportion. Accordingly, we found in the lees of untreated wines, as also in the lees of treated wines, tartrate of lime in addition to the normal potassium salts (tartrates), but obviously in smaller amount. We have examined several untreated wines and what may be called as the normal amount of potassium sulphate was found to range from 0·056 per cent. to as much as 0·15 per cent. It is clear, therefore, that potassium sulphate is a normal constituent of wine, amounting at times to nearly half the quantity contained in the so-called "plastered" wine.

The French Government have a prohibition order forbidding the importation of wine into France containing more than 2 grammes per litre (0·2 per cent.) of potassium sulphate, but the wine thus imported is chiefly used for blending, and for this purpose a specific and delicate character is not indispensable. The restriction appears to have been the outcome of economic rather than of hygienic considerations. In bad years in the vintages of France the regulations in regard to the character of imported wines are less rigidly imposed than in prosperous seasons. The question as to whether sulphate of potassium, in the quantity in which it occurs in wine, is responsible for injury to health has been the subject of considerable discussion for some time, and recently it has been revived in France, notably by M. Lancereaux in a paper read before the Academy of Medicine. It may be pointed out that treatment with sulphate of lime is not peculiar to sherry but, as we have found by experiment, it is applied also to certain clarets and to Marsala. M. Lancereaux's views and the discussion arising upon the public expression thereof will be found conveniently summarised in the following numbers of THE LANCET: Sept. 18th, 1897, p. 748; Oct. 23rd, 1897, p. 1083; Nov. 13th, 1897, p. 1289; Dec. 4th, 1897, p. 1486; and still more recently in THE LANCET, April 2nd, 1898, p. 966. M. Lancereaux concludes that in Paris the principal cause of cirrhosis of the liver is wine, and that in general use is red wine. Since, as he affirms, those addicted to the use of spirits are rarely affected with cirrhosis, alcohol, he holds, cannot be assigned as the cause of this disease in wine-drinkers. He considers that the potassium salts are in fault, and apparently in experiments in which potassium salts (it is not stated which) were administered to animals they died and showed on examination a cirrhosis "*bi-veineuse*." M. Lancereaux maintains in conclusion that wine—and especially plastered wine—is the cause of atrophic cirrhosis, and that it would therefore be well to prohibit the plastering and sulphating of wine. M. Vallin adversely criticised these views before the Academy and he thought it was necessary to have confirmation of the views held by M. Lancereaux. He pointed out that beer and gin, although they cause cirrhosis, only contain a small amount of potash salt. He held that cirrhosis was due to excessive alcoholic drinking altogether without reference to the salts of potash.

M. Laborde at a subsequent meeting of the Academy maintained, in opposition to M. Lancereaux, that the cirrhosis of the intemperate is caused by alcohol and not by potassium sulphate in wines. He further made the very important observation that, as is well known, the potassium salts are rapidly eliminated, and he added that they are not injurious except in very large doses. By administering as much as three ounces of potassium sulphate in fifteen days to dogs M. Laborde found that the dogs' health continued perfectly good. Lastly, he added, it must be borne in mind that everybody takes in his daily food from 75 to 105 grains of potassium salts and at this rate cirrhosis ought to be universal. M. Richet, at a still more recent meeting of the Academy of Medicine, expressed the view that there is no reason to think that the toxic qualities of wine are due to the potassium sulphate and referred the occurrence of cirrhosis to the effect of alcohol on the liver and gastric centres. He concludes, however, that M. Lancereaux is probably correct in considering that potassium sulphate is to blame in the production of the cirrhosis of drunkards.

In commenting upon M. Lancereaux's views the *British Medical Journal*, in a leading article in its issue of Oct. 30th, 1897, p. 1284, says: "The distinguished French pathologist (M. Lancereaux) is doubtless more or less correct in his conclusions about wine and hepatic diseases in Paris and it would appear that 'some' kinds of beer contain the noxious

Digitized by Google

salt."[3] "Unfortunately," our contemporary continues, "we once more face negative evidence." "He implies that spirits, especially absinthe, do not contain the salts. Absinthe-drinkers do not get cirrhosis. What, however, causes the disease in the British drunken operatives? Do some spirits, like 'some beers,' contain potassium sulphate? The matter is worth investigation. Till it is made clear we doubt if British physicians will abandon the theory that spirits—at least, British spirits—cause cirrhosis through the direct injurious action of alcohol on the liver." Referring to this article Dr. Thorowgood[4] expresses the belief that lime salts "are the constituents of wine that do more than the potassium sulphate to induce fibroid and cirrhotic change in organs." On the other hand, Dr. Luff[5] writes: "Although I am open to conviction as to the possibility of potassium sulphate contained in wines being a factor in the production of cirrhosis in excessive wine-drinkers—a point which, in my opinion, is not by any means established by the investigations of Lancereaux—yet I feel fairly confident that the lime salts contained in wine cannot be held responsible for the production of cirrhosis as is suggested."

In considering these expressions of opinion it is interesting to record that the men engaged in the bodegas in Jerez drink sometimes as much as six litres of light sherry per diem (10½ pints) and yet cirrhosis is unknown among them. This quantity amounts to a maximum daily consumption of 20 grammes or 308 grains of potassium sulphate. There is also to be considered the interesting and important fact that potassium sulphate occurs universally in almost all articles of diet and, as is pertinently pointed out by M. Laborde, cirrhosis, if it be due to potassium salts, should be universal. In the British Pharmacopœia potassium sulphate is contained in pulvis ipecac., pil. colocynth. et hyoscyami, pil. colocynth. co., and pil. ipecac. cum scilla. It is distinctly diuretic and "a valuable saline purgative" administered in doses varying from 10 to 60 grains. The average quantity in a bottle of sherry of one-sixth of a gallon is 40 grains. After all, the potassium sulphate in sherry is an equivalent of the potassium tartrate originally present in the wine, which latter salt presents similar therapeutic properties to the sulphate. Potassium sulphate is further described as mildly cathartic, usually operating without irritation, and as a useful purgative in jaundice and dyspeptic affections. Lastly, potassium sulphate "is a hepatic and intestinal stimulant of considerable power, but its action on the liver is uncertain."

Various Types of Sherry.

As has already been indicated there are a great many varieties of sherry and in what particulars each and all differ will be seen from the following analyses of a few selected types. It should be added that the samples to which reference is here made and all other samples the analyses of which are given in this inquiry were obtained personally on the spot by our Special Commissioner. The analyses were made in THE LANCET Laboratory and are perfectly independent of those published elsewhere or at any previous time.

Sherry No. 1.

	Per cent.
Solid matters	1·44
Sugar	0·18
Potassium bitartrate	0·08
Tartaric acid	0·36
Acetic acid	0·10
Mineral matter	0·46
Potassium sulphate	0·39
Alcohol by weight	13·15
,, ,, volume	16·24
Proof spirit	28·46
Alcohol in volatile ethers	0·0228
,, ,, fixed ethers	0·0320
Total alcohol in ethers	0·0548

This wine was a pale delicate dry wine of the "fino" type and of light alcoholic character and suitable for drinking with meals. It is almost as light to drink as claret. The sugary contents are practically *nil*, the wine being correctly described, therefore, as "brut." It is an "amontillado" and possesses the fragrant and delicate character of the celebrated Montilla wine.

Sherry No. 2.

	Per cent.
Solid matters	2·20
Sugar	0·215
Potassium bitartrate	0·08
Tartaric acid	0·343
Acetic acid	0 126
Mineral matter	0·55
Potassium sulphate	0·52
Alcohol by weight	14·82
,, ,, volume	18·25
Proof spirit	31·99
Alcohol in volatile ethers	0·026
,, ,, fixed ethers	0·038
Total alcohol in ethers	0·064

Like the last this is an "amontillado" with a slightly-increased proportion of solid matters and sugar. It is a light, delicately-flavoured wine suitable for drinking with meals much in the same way as claret.

Sherry No. 3.

	Per cent.
Solid matters	2·66
Sugar	0·60
Potassium bitartrate	0·17
Tartaric acid	0·382
Acetic acid	0·12
Mineral matter	0·57
Potassium sulphate	0·47
Alcohol by weight	13·92
,, ,, volume	17·17
Alcohol in volatile ethers	0·0333
,, ,, fixed ethers	0·0423
Total alcohol in ethers	0·0756

This wine comes midway in character between a "fino" and an "oloroso," though perhaps inclining to the side of the latter. It is an excellent after-dinner wine with greater "vinosity" than the previous specimen, and accordingly the ethers occur in higher proportion.

Sherry No. 4.

	Per cent.
Solid matters	2·87
Sugar	0·65
Potassium bitartrate	0·13
Tartaric acid	0·41
Acetic acid	0·10
Mineral matter	0·70
Potassium sulphate	0·65
Alcohol by weight	15·67
,, ,, volume	19·28
Proof spirit	33·79
Alcohol in volatile ethers	0·0341
,, ,, fixed ethers	0·0418
Total alcohol in ethers	0·0759

A similar wine to the last, with slightly increased body and alcoholic strength. An after-dinner wine.

Sherry No. 5.

	Per cent.
Solid matters	6·75
Sugar	3·85
Potassium bitartrate	0·16
Tartaric acid	0·336
Acetic acid	0·087
Mineral matter	0·595
Potassium sulphate	0·47
Alcohol by weight	16·46
,, ,, volume	20·24
Proof spirit	35·47
Alcohol in volatile ethers	undetermined
,, ,, fixed ethers	,,
Total alcohol in ethers	,,

This is an excellent type of a medium "oloroso" wine, full-bodied, sweet and darker coloured than the previous specimens. It is known as "palo cortado." The ethers

[3] All kinds, we believe, since water containing the highest possible proportion of sulphate of lime used in the treatment of wines is particularly selected for the production of beer, and the interaction of sulphate of lime with the potassium salts of malt would result in the formation of potassium sulphate in the beer and the sedimentation of insoluble lime salts which, as in the case of sherry, serve in falling to clarify and to refine.

unfortunately were not determined as the experiment failed on account of the apparatus breaking.

Sherry No. 6.

	Per cent.
Solid matters	5·45
Sugar	1·03
Potassium bitartrate	0·26
Tartaric acid	0·52
Acetic acid	0·20
Mineral matter	0·86
Potassium sulphate	0·76
Alcohol by weight	18·85
,, ,, volume	23·10
Proof spirit	40·48
Alcohol in volatile ethers	0·0745
,, ,, fixed ethers	0·1410
Total alcohol in ethers	0·2155

An old nut-brown sherry and an "oloroso." Dry to the taste but full of pleasant character (the so-called "vinosity") and accordingly containing a remarkably high proportion of wine ethers. It possesses the peculiar inimitable flavour and bouquet of fine old matured sherry. Vintage 1865.

Is Sherry a Pure Wine?

There is no point in any single particular in the foregoing analyses which may fairly be regarded as evidence of adulteration. Nor does an inspection of the entire methods concerned in the production of sherry from the vineyards to the bodega give any suspicion of anything being carried on that is not honest and publicly open to view. As will have been gathered from the present article, there is no mystery about the production of sherry and the interested visitor may easily obtain an entry into any of the great producing bodegas, and at vintage time Jerez is one of the most interesting sights in the south of Spain. Our Commissioner visited most of the large bodegas in Jerez, San Lucar, and Montilla, where sherry-growing is carried out on a gigantic scale. He was met with the greatest courtesy by the sherry-growers—and three-fourths of the industry is carried on by English people—and every step in the interesting processes was shown to him, as were all other operations incidental to the production of sherry. Perhaps the most satisfactory and reassuring feature in this connexion is that nothing is concealed, the processes throughout from beginning to end are readily explained and where possible practically demonstrated. This, of course, cannot be said in regard to the production of many wines, nor is it fair to expect altogether that such should be the case. Still, where there are no secrets concerned in the course of production it is clear that the grower is convinced and confident of the honesty of his product. There are two facts in connexion with the production of sherry which are open to be construed as adulteration. The first is the addition of sulphate of lime to the crushed grapes before fermentation and the second the addition of a small proportion of spirit to wine intended for export. Against the former we do not think that a rational objection can be raised so long as the treatment is kept within limits, and this is invariably so. It may be called an artificial recourse, but so also is the adding of sugar-candy to champagne to make it sparkling or of gelatine, clay, and so on for the purpose of refining wines, beers, &c. We have described how the same thing may be to some extent naturally effected by the simple occurrence of an unusual proportion of vineyard dust adhering to the grapes prior to pressing. We venture to suggest that this has been the origin of the so-called "plastering process." The sulphate of lime employed is a natural constituent of the soil contiguous to the vineyards. The question is, Can this be regarded in the light of adulteration or fraud, since it does not add in any way to the bulk of the wine nor does it make it poisonous? On the contrary, it refines the wine and increases its power to develop those fragrant ethers which give to the wine its peculiarly pleasant characters in regard to bouquet, flavour, and agreeable stimulating qualities. Whatever character a sherry may possess this is due entirely to the produce of the grape and to no foreign addition. When, for example, a sweet wine is demanded by the public taste a certain proportion of "dulce" is added; dulce itself being a concentrated grape liquor, while a similar liquor imparts colouring consequent upon the caramelisation produced during the concentration by boiling of the grape sugar. It has been said that wine treated with sulphate of lime contains free sulphuric acid. This, in our experience, is not true, since in the whole of the wines examined the potassium acid tartrate was not entirely removed and the ash obtained on evaporation and incineration of the solid matter was invariably alkaline. This could not be in the presence of free sulphuric acid or acid sulphates. Further, we found that tartaric acid is without action on sulphate of lime. As we have said, the potassium acid tartrate produced in wine by this treatment is largely removed in favour of potassium sulphate. There is very little therapeutic difference between the two salts, both are diuretic and purgative and are rapidly eliminated from the system. The former, however, is more likely to produce increased alkalinity of the blood than the latter. As is well known, in very old wines the acid tartrate of potassium is nearly absent, being thrown out in the form of crust.

Then, with regard to the addition of spirit. This in the majority of cases is small, and in some cases, as in Sample No. 1 in the Report, is omitted altogether, this being a "brut" natural wine, as otherwise much of the sherry could not be imported into this country at the cheap rate of duty (1*s.* per gallon of a maximum alcoholic strength of 30° proof spirit; when much under this strength sherry will not travel satisfactorily). Some estimate of the spirit so added will be found by comparing the quantity of alcohol in "mosto" and in a light imported wine as recorded in the analyses in a previous part of the present article. It will be seen that this addition amounts to about 2 per cent. by weight, although some account must be taken of the normal increase which takes place in alcoholic strength by keeping. It is a curious fact that sherry in keeping develops a slight increase of alcohol as the time advances. All spirit added to sherry, however, is obtained from wine itself, corn spirit in Spain being quite a superfluity, since wine spirit can be produced so cheaply and in unlimited quantity. Moreover, the importation of German spirit into Spain is made practically impossible by a prohibitive duty. Good brandy — that is, a genuine wine-distilled spirit — is being produced in Spain in commercial quantities which it is to be hoped will successfully compete with the stuff erroneously called brandy, not to say Cognac, but of which not a drop has been derived from the grape.

It follows as the outcome of our inquiry that it cannot be correctly said that sherry in any particular contains a single ingredient foreign to its composition. We again lay stress on the fact that in coming to these conclusions we are speaking of vinum Xericum, the vino de Jerez, or the wine produced in Spain generally known as sherry, and not of those fictitious wines which are produced, or rather concocted, only too freely elsewhere. Indeed, it is true to assert that Spain could not profitably produce fictitious wines, so essentially and peculiarly is it a country where the grape grows luxuriantly and abundantly.

PLYMOUTH PUBLIC DISPENSARY.—The 100th annual meeting of the Plymouth Public Dispensary was held on Oct. 19th. The report stated that 3345 patients had been treated during the past year and that 579 patients had been visited at their homes. The financial statement showed that in the charitable department the receipts were £903 and the expenditure £987. In the provident department the income and disbursements both amounted to £129. It was decided that the centenary of the institution should be celebrated next month.

LITERARY INTELLIGENCE.—Mrs. Alec. Tweedie has in the press a Life of her father, the late Dr. George Harley. The book is to be published by the Scientific Press, Limited.—Messrs. Williams and Norgate's circular announcing new books includes the following: "Der Luftdruck in den pneumatischen Kammern und auf Höhen: Vom ärztlichen Standpunkt" (G. v. Liebig). "Kritik der Echtheit der Paracelsischen Schriften" (K. Sudhoff). "Vergleichende Anatomie der Wirbelthiere mit Berücksichtigung der Wirbellosen" (C. Gegenbauer). "Handbuch der Cystoskopie" (L. Casper). "Anleitung zur qualitativen und quantitativen Analyse des Harns," tenth edition (Neubauer and Vogel). "Bacterium septatum und dessen Beziehungen zur Gruppe der Diphtheriebacterien" (T. Gelpke). "Handbuch der Unfallerkrankungen" (C. Thiem).

THE LANCET.

LONDON: SATURDAY, OCTOBER 29, 1898.

WE are all hoping that a better state of things is coming between friendly societies and their medical officers. The right of combination on the part of the working classes and the claim for any advantages which the principle affords in the way of organised schemes for procuring medical attendance have never been disputed by the medical profession. On the contrary, they have been recognised as they have scarcely been recognised by any other profession. This of itself constitutes a claim on the part of medical men for consideration and justice, not to say generosity, on the part of the friendly societies. Great objection has been taken to those huge combinations which are apt to become tyrannical in their dictation of terms and which, in fact, have come in many cases to be machines for sweating individual medical men and dealing a serious blow at the independence and dignity of the profession. Still the profession has preserved moderation of temper and of argument, and in regard to its supreme duty it has appealed for guidance to the General Medical Council, which is the last court of appeal in questions deeply affecting the methods or the ethics of medical practice. The Council has not yet responded to the last appeal of those who have felt the injustice of some of these huge combinations. But it is to be gathered from its last *interim* report that the Council is not without hope of being able to do something in the way of restoring that harmony which used to exist between ordinary and reasonable combinations for medical attendance and the medical profession. It is understood, too, that on the side of the friendly societies there is a genuine disposition to do justice to their medical officers and to remove all reasonable causes of complaint and friction. It is obvious that in dealing with large societies having a membership to be counted almost by millions there must be patience on both sides. Time is necessary to form and to ascertain opinion. We are quite ready to make all such admissions. Meantime it is well to take notice of individual cases which illustrate the evils of which medical men complain. A fair study of them will enable both the General Medical Council and the friendly societies to understand the strength of the complaint that in the development of friendly societies the profession has not been treated generously, whether judged with reference to the increased cost and completeness of medical education or the increased demands of friendly societies for efficient attendance and the increased means of their members to pay more adequately for it.

A case in point is reported from Evesham, in which Mr. ANTHONY HERBERT MARTIN and Mr. JOHN SAMUEL SLATER, Surgeons to the Court Vale of Evesham (No. 4648) of the Ancient Order of Foresters, were the plaintiffs in a county court action and the trustees of the Court Vale were the defendants. The action was to recover a certain sum due to the plaintiffs. The defendants admitted the sum but claimed to set off against it a sum of £4 11*s.* 6*d.*, an amount which they had had to pay on behalf of members for medical attendance in consequence of the surgeons' neglecting to attend them. The neglect, on the theory of the defendants, was in this wise. The plaintiffs had acted as medical officers of the court for twenty-five years for the sum of 5*s.* per annum for each member. On May 24th Mr. MARTIN received notice of a meeting of the society—the usual quarterly meeting—at which the reduction of his fees per member from 5*s.* to 4*s.* would be proposed. He attended the meeting and stated that if such a resolution were passed he would then and there resign. The resolution was passed and he resigned for himself and his partner, declining to see the members except as private patients. The defendants considered themselves entitled to a month's notice. As this had not been given they construed non-attendance into neglect and acting on a rule of the society against neglect (Rule 16), they deducted from the amount due to the plaintiffs the sum of £4 11*s.* 6*d.* which had been paid to other surgeons for attendance on cases between June 8th and July 8th. This was the only amount in dispute between the plaintiffs and the defendants and gave rise to the action and the counter-action. The whole question turned on the right of the medical officers to resign without notice. The terms of the contract expressly enabled the society to dismiss its medical officers without any notice whatever. Nothing was said about the notice of resignation to be given by the medical officers. The judge took the very natural view that what was fair for the society was fair for the medical officers. "In the absence of any custom in the case ..... I come to the conclusion," he said, "that the contract is a contract terminable at pleasure by either side. ..... It provides for no notice being given to the doctor ..... and he may be summarily dismissed. I conclude that the doctor has a similar right of determining his office. I therefore give judgment for the plaintiff." He further allowed counsel's consultation fee. Mr. Smith, on behalf of the defendants, reserved the right to appeal.

The *Evesham Journal* of Oct. 22nd, to which we are indebted for a good report of this interesting action, gives also an equally interesting report of the Foresters' annual dinner. The incidents of this action and the moral of it were referred to by various speakers, mostly, we think, in sympathy with the medical officers. We regret to learn that the society is not too rich. The members have to economise or to increase their subscriptions. It is of course much more easy for them to reduce their medical officers' fees than to increase their own subscriptions. But the members were ill advised in regarding the reduction of the fees of the surgeons who had served them for a quarter of a century as economy. This miserable attempt to reduce medical fees already too small is a fruitful source of the discord which obtains so largely between medical men and these societies. One speaker, Mr. GEOFFREY, said, "If they get a good day's work from a man let them give him a good day's pay. Let them treat a man as they would be treated themselves." We commend this admirable advice to this society and to all the friendly societies. Of all economies that is the worst which would starve and

Digitized by Google

sweat medical men. In this particular instance the result is melancholy. They have dismissed gentlemen of long service and of high standing in the community. It is true they have got another medical officer — a stranger, we gather — to take the reduced fee. We pass no judgment on him. No doubt he has a "conscientious belief" that he is doing what is right. But we have a deep conviction that neither he nor they are "helping along the interests of Forestry."

AN anonymous correspondent, "M.D.," in a letter to the *Times* of Oct. 24th, gives some interesting particulars respecting the results of his examination of 100 boys who were just entering a public school. They were, with scarcely an exception, supposed to be healthy boys and were between thirteen and fifteen years of age. It is certainly very startling to find that over 60 per cent. of these boys were suffering from deformities ranging from lateral curvature of the spine and pigeon-breast to flat-foot, even though we recognise that they were at the age when infantile maladies and unnatural school postures begin to tell their story. No stronger plea for proper physical exercise from the time of leaving the nursery has ever been quoted, even if we allow that the examiner was a little over-severe in his examination. Cases of serious disease were only 2, but both of these were affections of the heart. Two boys were ruptured, but it is not stated in the columns of our non-medical contemporary whether these were congenital cases. We assume them to have been and to have gone unnoticed before the medical examination. Slight varicocele was found in 14 cases. Defective vision was detected in the large proportion of one-fifth of the 100, and one boy was colour-blind. Defective hearing was found in 9. The most unexpected item in the list, however, is the number of cases—22—in which albumin was present in the urine. The subsequent history of these 22 boys, as well as a medical account of their antecedents in regard to the infectious diseases, would be most interesting and would throw a flood of light on the pathology of the so-called "functional" albuminuria of which we know so little. We hope the writer will use the unique opportunity which presented itself to him to fill up this hiatus in medical literature.

Apparently the "average" boy in height, weight, and chest girth is a very rare specimen, and this we should expect, although it sounds paradoxical to say that the average boy is the rare boy. But between thirteen and fifteen years of age a boy is on the eve of accession to puberty, at which age the rate of development is very variable and averages are rather of statistical than personal value. There is a marked difference even in standard tables of averages at these ages, and as the writer states that he has included every variation in the height and weight it would be necessary in estimating the value of his table that we should be informed which standard he has taken as his basis. Under the heading of "height" 52 boys are stated by "M.D." to be above the average height and 39 to be below it in his 100 cases. At fourteen years of age QUETELET gives 57·3 in. as the average, the Anthropometric Committee 59·3 in., and MACLAREN 60·7 in. There is obviously so wide a discrepancy between these calculations that "M.D.'s" statistics must be read with a critical judgment. QUETELET'S cases were Belgians; the Anthropometric Committee took their average from the general population of Great Britain; whilst MACLAREN, like "M.D.," drew his average from 100 boys. We should like to know the limits employed by "M.D." in deciding on the maximum and minimum measurements of the long, lanky, and narrow-chested boy and the stumpy, heavy-looking, and broad one. The variation in weight in British boys is much less than in height, as at fourteen years of age there is only a difference on the average of 1 lb. between the estimates of the Anthropometric Committee (92 lb.) and MACLAREN (93 lb.); and the same tables show but little difference in chest girth, being respectively 28½ in. and 29½ in. In "M.D.'s" cases 40 per cent. were above the average in weight and 53 below it, whilst the chest measurement showed 24 above and 68 below. These figures are more suggestive than the mere question of height. The tables of the Anthropometric Committee are by far the most comprehensive and should be adopted as the standard in any further investigations on the condition and development of any members of the community. Researches on these lines are of the greatest utility, not only to the boy and his teachers, but also to his parents and the medical officer of the school, and might with advantage be extended to all classes of people who work practically under similar conditions.

AS announced in our issue of Oct. 15th the Charity Organisation Society are giving a series of lectures upon the question of medical relief, and we congratulate them upon their efforts to promote a more healthy public opinion in regard to gratuitous medical work of all kinds. The first lecture, by Mr. LOCH on the growth of medical charities, was introduced by a speech from Sir WILLIAM BROADBENT which enhances the obligation of the public and the profession to him for the long and painstaking interest which he has displayed in this subject. He might well plead both want of leisure and of inclination to criticise and improve a system under which he has attained to high success. There is a strong, and in some degree a natural, feeling of this kind among hospital physicians and surgeons which greatly hinders the reforms which are needed. They do not seem to see that a better administration of hospital relief would do the hospitals good, and would save them from that suspicion which attaches to all undiscriminating forms of relief—all relief, that is, which is superfluous, which is not needed, and which does for people what they can easily do for themselves. We commend Sir WILLIAM BROADBENT'S views to his colleagues on the staffs of the metropolitan hospitals. He seeks to raise the reputation of hospitals by bringing them into coördination with all other forms of medical service, and especially with all provident forms of such service, so that every self-respecting working man and his family should have ready use of them when occasion requires. But he would not allow them to be used indiscriminately as at present. Like many other friends of the hospital system

Digitized by Google

he sees that its weak spot is the out-patient department, where abuses undoubtedly exist. And like many other sound observers of these abuses he is doubtful of the efficacy of the ordinary remedies for them which are in vogue at present. He is of opinion that the precautions against abuse are inadequate. A superficial inquiry into the means and circumstances of patients at the hospital is not enough. Any efficient investigation must be made at the homes of the patients. This is, of course, obvious. It is the opinion even of those who benevolently supply tea and coffee to out-patients that abuses exist, but detection of such abuses in the crowd of an out-patient room is practically impossible. The difficulty is that any efficient home investigation of the case of the thousands who attend the out-patient department would be very costly. Might not an object lesson in this work be given by some volunteers undertaking an inquiry into a limited number of out-patient cases in each hospital?

This is Sir WILLIAM BROADBENT'S suggestion and it is a valuable one. He is favourable also to the creation of a Central Hospital Board for the better discussion of questions which affect the support and efficiency of hospitals. But the board which he advocates is one not of outsiders but of representatives of hospitals of every kind and creed. His arguments formed a good preface to the address of Mr. LOCH, who estimated that after making all due allowances the number of persons relieved by London hospitals was not less than 2,000,000 a year. The fact is an appalling one and should make the most conservative supporter cry for a halt. Mr. LOCH made a powerful point in his argument against such wholesale and reckless help of the growth of other forces in the community which make it incongruous and indefensible. Chief among these was the development of the friendly societies. He reckoned that one in every three working men above the age of sixteen in London was a member of some such society. This is very creditable to the working classes and makes it only the more regrettable that the hospital system should lend itself to "loose and lumbering methods" of giving medical help. Mr. LOCH said, and with some truth, that the popular view of the hospital system at present was that it should be placed within the reach of all the poorer classes on demand and that practically any member of the artisan or labouring class or his family should receive free medical aid. Such a view is founded on a misconception of the very object of hospitals and is unworthy of the men who have built up the friendly societies of England. We agree with Sir WILLIAM BROADBENT that in urgent circumstances such men should have free admission to our hospitals, but we are equally clear that for all ordinary medical attendance they are capable of making their own private arrangements.

We have noticed Mr. LOCH'S address rather from the public than the professional point of view. The evils he describes so ably should be rectified on public grounds. It is in the public interest that all degrading and pauperising elements should be eliminated from medical charity. But we do not forget that the medical profession has the greatest right to demand the remedy of such evils. It works the medical charities, it does an amount of charitable medical work which no other profession does, and its "ready help is always nigh" for the necessitous and impecunious sick. But for this very reason it should be guarded from imposition and the great institutions which use its gratuitous services should see that they lend themselves to no abuse.

THOSE of our readers who have followed the accounts given in the daily press of the cases of plague having their origin at the Pathological Laboratory in the Allgemeines Krankenhaus of Vienna cannot but fe nat the event is one of those accidents from which great good or great evil may arise according as the lessons are taken to heart. The facts are as follows. For eighteen months past the members of the Austrian Commission who went out to India for the purpose of studying plague in its clinical and bacteriological aspects have been continuing their investigations and have performed numerous experiments with the object of deriving further light as to the exact relationship between the disease and the bacillus pestis, also having in view the possibility of devising some prophylactic or antitoxic method of treatment which might be available for the prevention and treatment of this excessively fatal disease. It appears that up to the last week or two some fairly successful results have been obtained as regards the second part of the investigation, and this had even gone so far that it had been suggested that the laboratory attendant who was engaged in looking after the inoculated animals should submit himself to preventive inoculation. To this, however, he demurred and the step was not taken. The question involved in the first part of the investigation has now unfortunately been answered only too precisely in the affirmative, and we are compelled to accept as the result of a most unfortunate accident the proof that the bacillus of plague, and this bacillus alone, is capable of initiating an outbreak of bubonic plague of the most virulent type.

In this instance we have the plague bacillus taken from plague patients, transported from India, and grown generation after generation in a laboratory where the utmost care must necessarily have been exercised to keep this micro-organism uncontaminated or unmixed with others grown in the same laboratory. These organisms, a number of cultures of which, we are told, showed various grades of virulence, were used to inoculate animals. Under ordinary circumstances and with reasonable precautions (such precautions as have been taken in the same laboratories for years) there was not the slightest danger of the spread of the infection through the animals; for it having been recognised that rats are often the vehicle by which the bacillus is carried, any animal-house or laboratory to which rats from the outside had access would naturally be condemned at once, and there is every reason to believe that Dr. MÜLLER and those associated with him were fully cognisant of this danger. It was a risk scarcely to be apprehended that an attendant thoroughly impressed with the necessity for taking certain simple and elementary precautions and fully understanding the danger attending such neglect should, while on duty, have brought himself into such condition that he was no longer able to estimate his danger. This, however, is what happened. An attendant who, perhaps unknown to those in authority, had gradually been deadening his sense of responsibility went to his work

Digitized by Google

in a condition in which he did not realise the danger to which he exposed himself through not carrying out simple precautions, though in his normal condition he would never have thought of neglecting them: and we have as a result the first case of plague infection occurring directly through the mouth. As Professor PALTAUF points out, the infection might have been absorbed from the hands or from the pipe the man was smoking being laid down on a surface to which plague germs had access.

The second act in the tragedy appears to have been due to hypersensibility rather than to any blunting of a feeling of responsibility, and we have in the case of Dr. MÜLLER and of the two nurses who attended on BARISCH an instance of devotion to duty overcoming all sense of danger and of the necessity for taking personal precautions. The extreme anxiety on the part of the actors in this terrible drama to carry out all the necessary precautions to prevent the further spread of the disease amongst those outside led to their own undoing, and there can be little doubt that had Dr. MÜLLER and the nurses taken more food, more rest, and more sleep they might all have been alive to-day, as even the pneumonic form of plague does not, as a rule, infect people in a good state of health, especially when they are placed under proper hygienic conditions and not actually engaged in plague work. So far this outbreak has claimed two victims and another may succumb, but it appears probable that with this exception there will be no further cases of death from plague in Vienna. It is perhaps too early to speak with any degree of assurance on this point, but from the statements of those who are best acquainted with the circumstances of the case we are led to hope that no further ill results will directly attend this tragic mishap.

The great lesson to be gathered is that where the organisms which cause this deadly disease are being experimented with, and, in fact, wherever they are present, whether accidentally or not, the use of no precaution, either great or trifling, is to be neglected for the purpose of confining the organisms to the sphere allotted to them. That this can be done when very elementary precautions are taken we have ample evidence, especially where experimental work only is concerned, but it must be pointed out that the principles which ought to govern the work of every laboratory must be applied with equal strictness in everyday life on the outbreak of a specific infective disease. Who but a fool would think of "handling" a cultivation of anthrax bacillus or of inhaling the diphtheria bacillus or the bacillus of tuberculosis as found in a laboratory? Nevertheless, under ordinary conditions of life there are men who are frequently handling carcasses in which anthrax bacilli are present in enormous numbers and who after a time become so careless that they continue to do their work with cut hands or scratched arms, with, of course, but one inevitable result. There are people who, owing to carelessness on their own part or on that of others are exposed to infection through the throat and lungs by the organisms which give rise to tuberculosis or diphtheria. Such stories as the tragic one from Vienna should make such people think. As most of the papers point out, and as our own information goes to show, Dr. MÜLLER behaved throughout with a heroism which fortunately is not rare in the medical profession, and it cannot but be felt, after reading the full accounts of what he did and what he suffered, mentally and physically, that his conduct gives a very direct lie to an insinuation which we have often been ashamed to read. He at any rate cannot be put down as amongst those who are brutalised by the carrying on of experimental work. A last word. Some will say that the responsibility of introducing into Western Europe a disease which has not for some time invaded it in any other way is greater than that involved in watching the ravages committed by epidemic disease amongst us without making special efforts to cut short such diseases. This is a point, as Sir ROGER DE COVERLEY says, on which much might be said on both sides, but we have no doubt ourselves on which side right lies. We hope that whilst the teaching of this serious accident is taken thoroughly to heart by those engaged in carrying on experimental investigations attention will be drawn to the still wider question of the prevention of disease due to well-recognised micro-organisms, and that the interest which attaches to the deaths in Vienna may not distract attention from the need which there is for remembering that micro-organismal diseases which are at all times with us and in our very midst may for the most part be prevented by the adoption of fairly well-known and reasonable precautions.

Annotations.

"Ne quid nimis."

THE SICKNESS AMONG THE TROOPS FROM THE SOUDAN.

As we have repeatedly said, it was to be confidently expected, in accordance with our previous experience in connexion with campaigns in tropical and sub-tropical climates and with that of similar expeditions conducted by every other nation, that a considerable amount of sickness, and notably of enteric fever, would appear among the troops returning from the Soudan. Compared with similar expeditions undertaken by other Powers, or even with those previously undertaken by this country in Egypt, the total amount of sickness and the number of cases of enteric fever on the present occasion have so far been less than might have been anticipated. It will be remembered that there was a large amount of enteric fever among the British troops after the Egyptian campaign of 1882 and also after the second expedition to Suakin. It is, unfortunately, always the case that an army in the field suffers far more from sickness than from the assaults of the enemy to which it is opposed. The late expedition to the Soudan was a long and very arduous one, added to which there was other continued exposure of the troops to climatic heat and the unhealthy conditions to which they were unavoidably subjected. Although losses from sickness are practically unavoidable under such circumstances, still it must not be forgotten that their amount is very sensibly lessened in proportion to the forethought and care bestowed on perfecting the hygienic and medical arrangements in the field. The French campaigns in Tonquin, Madagascar, and elsewhere, and still more recently the very lamentable experience of the Americans in Cuba, contrast very unfavourably with those of this country in Ashanti, Egypt, and the

Digitized by Google

Soudan. We have gone on improving of late years in respect of the sanitary and medical preparation, organisation, and management of our military expeditions. We have, at any rate, reached a standard that enabled the Sirdar in his Omdurman despatches to declare his belief that "the minimum of pain and maximum of comfort procurable on active service in that country had been attained. Still, do what we may, the use of unwholesome and contaminated water on the part of the troops cannot be altogether prevented, the effect of climatic heat upon men unaccustomed to it has to be encountered, and the soldiers have for some time to subsist on tinned and preserved foods and to face the hardships and fatigue incidental to campaigning. The time for the disease-toll to be exacted comes when the physical wear and tear and the excitement and strain of the nervous system have abated or passed away, and the Grenadier Guards as well as various other corps returned from the Soudan are now paying it as a result of their gallant service there. There are, we believe, about 100 men of the 1st Battalion of the Grenadier Guards in hospital at Rochester-row, of whom between 30 and 40 are suffering from enteric fever, in addition to about 40 cases of sickness of different kinds distributed between Cairo, Gibraltar, and Netley. At Cairo there is a large number of sick in hospital belonging to the recently returned force from Omdurman and the Soudan, and at Alexandria there are also several cases in hospital. We much regret to notice that two young officers, both of whom were present with their regiments at the battle of Omdurman, have since died from enteric fever at the Ras-el-tin Hospital, Alexandria. Second Lieutenant I. V. L. Maunsell, of the Lancashire Fusiliers, who was a very fine promising young officer, is a son of Surgeon-General T. Maunsell, C.B., the Principal Medical Officer at Malta, to whom we venture to express our sympathetic condolence.

CONSCIENTIOUS OBJECTION BY WHOLESALE.

No better illustration of the difficulty often experienced in drafting a clause of a Bill in Parliament so that it shall not hopelessly fail in carrying out the objects of its promoters can be found than is offered by the so-called "conscience clause" of the Vaccination Act. The avowed object—both of Sir Walter Foster, who originally proposed the clause, and of Mr. Balfour, who adopted it—was to prevent a mere mechanical presentation of objections in a multiplied and stereotyped form, such as an organisation like that of the Anti-Vaccination League could easily promote if the opportunity were given to it for doing so. To this end it was agreed that the person having the custody of the child—that is, the father, where there is one—should be required to personally present the objection before two magistrates in petty sessions, whom he was to satisfy (in what way the Act does not provide) that his objection was conscientious. The Keighley magistrates have lately shown how it is possible to comply with the letter of the Act and to evade its spirit. Keighley, as, no doubt, most of our readers are aware, is the town which first established a record in obtaining the recognition of local option in the matter of the non-enforcement of vaccination. It is now more than twenty years since the Keighley Board of Guardians of that day refused to carry out the Vaccination Acts and were committed to prison for their contumacy by the Court of Queen's Bench for one month. That episode was the first and last effort the Local Government Board made to enforce the coercive powers which the Board possesses in this matter and since that time vaccination has been a dead letter in Keighley. It became, therefore, interesting to see how Keighley would deal with the conscience clause. Would the numerous objectors in it refuse to avail themselves of it, as some of the stalwarts of the League have been recommending them to do, or would they present themselves before the magistrates and afford them the satisfaction as to their objection which the law requires? Then, again, the further question suggested itself as to what explanations would be necessary to satisfy the Keighley magistrates. These problems have been recently solved by the holding of what may be called a great field day for reviewing the Keighley army of objectors. On Oct. 4th no less than 693 recalcitrants, mostly women, we are told, presented themselves at the Keighley Court-house to four of the magistrates, who resolved themselves into two courts for the purpose of facilitating the business. In order to further meet the exigencies of the situation the magistrates, who appear to have been of an exceptionally accommodating disposition, decided that it was not necessary that the father should appear. As a matter of form each mother was asked whether her husband was a consenting party, and in many cases this system of abbreviated procedure was carried to its ultimate extent by his acquiescence being signified by a nod on the mother's part. The magistrates also decided that no oath should be required, thereby saving the payment of a shilling, and that it would satisfy them if the applicants when asked as to their conscientious objection merely replied in the affirmative, which, we presume, they were again allowed to do by a nod. We are not surprised, therefore, to learn from a local newspaper that the whole 693 applicants, by being taken in batches and by being expeditiously marshalled before the court by the superintendent of police, were polished off in a few hours. Thus, to make use of the phrase of the local reporter, the Keighley magistrates have certainly succeeded in reducing this formality "to its lowest and simplest terms." Indeed, the reduction is so complete that the formality may be said to have almost entirely disappeared in the process. The mothers, most of whom, we are told, carried babies, appear to have availed themselves of the period of waiting to have a congenial gossip, probably thinking that the children have escaped the risks of a bad arm at a not very burdensome cost, and the whole *mise en scène* was so successful that the drama is to be repeated in a fortnight's time. It will be interesting to see whether Leicester and other places where infant vaccination has been as much of a dead letter as it has been at Keighley will follow suit on the same lines, and whether the magistrates in these localities will be equally accommodating in facilitating the evasion of the intentions of the legislature. There appears to be as much difference of opinion in the anti-vaccinationist camp as there is amongst the magistrates as to how they should treat the Act. Probably the *genius loci* in each case will work out its own form of procedure on both sides and we shall thus have abundant opportunity of observing the operation of the first stage in the "tremendous experiment" upon which, in the words of Lord Lister, we have now embarked.

THE VENTILATION OF UNDERGROUND ELECTRIC RAILWAYS.

OUR remarks upon this subject in our issue of Oct. 15th have attracted considerable attention, and several lay papers have been prompted to apply for information to just those officials who should be able to give an assurance that a system of ventilation on the underground electric railways, over and above that established when the trains are in working order, had been provided. In the particular instance to which we referred—namely, that of the City and Waterloo line—we cannot allow that such an assurance has been forthcoming. It will be remembered that the point which we raised was based on a recent occurrence on this line which seemed to show that no extra precautions had been taken.

Digitized by Google

for securing the adequate ventilation of the tunnels in the event of emergency. "The best answer I can give to THE LANCET is to ask them"—so the general manager of this line is reported to have said in an interview with a representative of *London*—"how they think our workmen manage to live when repairing the line. ..... In the ordinary business of good and careful management our men make a minute inspection of the line at regular intervals and remain in the tunnel until the necessary repairs are completed. If there was any truth in this scare our men would have been as dead as door-nails long enough ago. Of course the story is altogether absurd." Clearly this is quite beside the question at issue. We never doubted that so long as the trains were running the condition of the air in the tunnels would be satisfactory. But in the event of the stoppage of the train in the tunnel this automatic system of ventilation would cease also and 200 or 300 passengers might soon exhaust the vital air. We held, therefore, and still hold, that a system of ventilation should be established providing against such a possibility. We do not gather that this is so from the information given by this responsible official. Neither is there comfort to be derived from the remarks offered by Sir Benjamin Baker to a representative of the *Standard*, for these remarks applied only to the Central London Railway, which differs in very important details from the City and Waterloo line. Sir Benjamin Baker is reported to have said that in the case of the Central London Railway there are at each station vertical shafts of from 20 to 30 ft. in diameter with electrical lifts moving up and down every two minutes. These act, and are designed so to act, like enormous pumps sucking up and restoring the air in the tunnels. This is very assuring in regard to the Central London Railway, but there are no intermediate stations on the City and Waterloo line, nor are there any electrical lifts "moving up and down every two minutes acting like enormous pumps sucking up and restoring the air in the tunnels." We have no wish to create any scare in this matter, but these statements do not in our opinion weaken in the slightest degree the force of our remarks. It would be much more satisfactory if the City and Waterloo Railway authorities could inform the public whether in the plans of their line duly approved by the Board of Trade there were adequate means provided for the ventilation of the tunnels in the event of the delay of a train by a breakdown. If there were not, and it be shown that there are at present no means of supplying air in the tunnels in such a case, then it is a regrettable and serious omission which demands prompt consideration and instant repair.

"THE FLOGGING MOVEMENT."

WE gladly call attention to a communication which appeared in the *Saturday Review* of Oct. 15th under the above heading. Amid the silly sentimentality and nauseous sympathy occasionally expressed in regard to cowardly ruffians who kick and beat their wives and children, commit deeds of violence, or cruelly maltreat policemen in their resistance against arrest, it is refreshing to light upon a bit of manly common-sense. Hardly a day escapes in which we do not come upon some description of such brutalities in the morning papers, and the experience of the out-patient departments of our hospitals could furnish numerous instances of a similar kind which never get into the papers. Everybody with any real knowledge of this class of criminals knows that there is nothing these bullies fear so much as the physical suffering which they do not hesitate to inflict on others. Despite of all that may be said to the contrary, flogging has a deterrent effect on ruffians of this class. They care nothing for imprisonment, which often has the result, moreover, of only adding further injury to that which their unhappy victims have already suffered at their hands. Besides, why should already over-taxed people have to bear the cost of "the keep" of these criminals while in jail? The poor but law-abiding citizen has no sympathy whatever with the unwholesome sentimentality of those faddists of the present day who gush over criminals of this sort but seem to ignore altogether the suffering which such criminals inflict on others weaker than themselves. Those who write and speak against flogging in cases of this kind have no practical knowledge of this class of criminals to lend any pertinence or weight to their opinion. We should like to see a year's trial made of a new and different method of dealing with them, and it would surprise us very much if a physical impression on the skins of such culprits did not result in making them and the class to which they belong think twice before committing crimes of this sort.

THE NEW POTTERY RULES.

IT is pleasing to record that the revised special rules recently issued by the Home Office in regard to certain dangerous trades have been met in a thoroughly conciliatory spirit by those most directly concerned. The new proposals have been fully discussed at a meeting at Stoke-on-Trent, where the Home Secretary, the manufacturer, and the industry were adequately represented. The proceedings, in fact, amounted to an arbitration where the *pros* and *cons* were discussed and where the experience of the practical man was consulted as to how far the suggested rules could be applied without interfering with the ordinary working requirements of the industry. The proceedings were presided over by an umpire, and there were several well-known authorities on the subject present. These included the inspectors of factories and certifying surgeons and, in fact, all who could realise the difficulties which the application of special rules might present. It is impossible to go into the revisions which were suggested and which in some cases were adopted in order to make new rules workable, but the following points are worthy of record. It appears that the total number of notices sent out by the Secretary of State as to the making of these special rules was 691, of which 416 related to the districts known as the potteries district, some ten miles long by three or four miles broad. There were 529 immediate acceptances of the special rules *in toto*, which in these cases were now enforced and being acted upon. Of the 162 original objections 78 had been withdrawn, leaving 84 to be dealt with by the arbitrators. The objections were in all cases reasonable and referred chiefly to what was considered an unfair distribution of imposition—to those cases, in short, in which much onus was thrown entirely on the manufacturer which ought to be shared by the operative. Thus there was no doubt that whatever a manufacturer did he was not helped by the personal cleanliness or care of the workers. In regard to the rule providing for the monthly examination of all women and young children by the certifying surgeon it was submitted that the rule should be modified by adding that the cost of such examination should not fall on the employer. This suggestion must remain in abeyance since there was no power to insert such a clause without further legislation. In regard to the rule providing that certain processes should not be carried on without the use of exhaust fans for the effectual removal of dust the manufacturers propose the insertion of the words "or other efficient means" after the word "fan," which should apply to all processes, the means to be approved in each particular case by the Secretary of State and under such conditions as he may from time to time prescribe for the effectual removal of dust. This after much discussion was agreed to. A modification providing for washing conveniences was also agreed to. Mr. Dugdale, Q.C., the Recorder of Birmingham, in his concluding

Digitized by Google

remarks as umpire tendered his best thanks for the way in which every suggestion made had been met by the gentlemen on both sides. On this account there had been the saving of a great deal of expense and friction, which were very undesirable elements in matters of that kind, and he certainly thought that the costs of the arbitration and the award should be borne under these circumstances by the Treasury. To this we will add that it is indeed most gratifying that a conference of this kind, beset with so many interests and points at stake, should have been brought to such a satisfactory issue and that the various important matters were discussed in a spirit thoroughly in accordance with the weal of both employer and employed.

"TYPHOID SPINE."

DR. W. S. NEWCOME has published an interesting case of "typhoid spine"—an affection the nature of which is disputed—in the *International Medical Magazine of Philadelphia*, September, 1898. Some have doubted the existence of such a condition, claiming that some complication, such as lumbago, is present in the convalescent stage of typhoid fever; others believe that it is due to some inflammation around the spinal column—"perispondylitis"; others that it is due to neuritis; others that it is hysterical. Dr. Osler states that "even if the great majority of these cases are hysterical some may be due to alterative changes of the disease." Inflammations of bone occur much more frequently after typhoid than any other fever. This lends some support to the second theory; but neuritis might also be produced by this spinal inflammation, and many cases of distinct neuritis have been reported. There have been no necropsies to throw light on the subject. Dr. Newcome's patient was a girl, aged seventeen years, who had an ordinary attack of typhoid fever. Towards the end of the fever she complained of pain in the back and thought it was due to cold which had been applied to reduce the temperature. It entirely disappeared and she was able to walk about. About two weeks afterwards she was seized with a severe pain in the lower part of the back radiating towards the hips. She could not lie down, and when standing was bent forward and drawn to the right side. The least motion was painful. She improved slowly and in a month was able to move about with little pain. Bicycle riding was ordered to "straighten her spine." Relapses occurred. Salicylates, acetanilid, salol, belladonna, bromide, and trianol were tried without success; finally morphia had to be given to relieve the pain. There was great tenderness over the second and third lumbar vertebræ and she was still bent forward and to the right. Extension weights of about 8 lb. were attached to each foot with a view to decrease the strain on the spine. In about four weeks all tenderness had disappeared. She made a complete recovery.

THE LONDON WATER-SUPPLY.

AT the meeting of the London County Council on Tuesday last a report was presented by the Water Committee. It was decided, however, to defer the discussion and consideration of the important proposals contained therein until Tuesday next, Nov. 1st. The preliminary question to be decided turns on a matter of procedure—namely, as to whether the Council will continue to wait for the report of the Royal Commission before taking any action in the direction of legislation or whether it will at once formulate its proposals and lay them before Parliament in the coming session. We believe that the report urges the necessity of pressing forward the old policy of the Council to acquire the eight metropolitan water companies, and in this connexion stress is laid upon the fact of the breakdown of the East London supply this summer. The report contains proposals as to immediate remedies and as to future supply. In regard to the former provisions are laid down authorising the Council to proceed forthwith with the connecting and laying of mains and other works necessary in order to enable it to protect any part of the metropolis from want of water. In regard to the latter it is recommended that "a Bill be promoted in the coming session of Parliament for the purpose of empowering the Council to bring an additional supply of water to London from the watersheds of the Wye and Towy on the general lines of the water committee approved by the Council April 21st, 1896, in so far as it applies to the Wye section of the engineer's scheme."

THE HYGIENE OF THE THEATRE.

WE learn that the authorities at Drury Lane Theatre, acting on the advice of Mr. Edwin O. Sachs, are setting the example of improving the hygiene of the mysterious regions of the theatre behind the curtain by introducing constructional ironwork to replace woodwork as much as possible and wire cables to replace the ropes. This should materially affect the accumulation of dust on the stage. The propelling power which Mr. Sachs has introduced is to be electricity and a great deal of manual labour will henceforward be avoided and thus the overcrowding of the stage should be less. To-day a pantomime requires some 100 to 150 stage hands alone, quite irrespectively of property men, and improved forms of stage construction are already being employed on the Continent, hydraulic power being in general use. The dampness occasioned by the constant leakage of water has, however, in Mr. Sachs's opinion, counterbalanced some of the benefits of improved construction, but he hopes that the substitution of electricity will obviate this defect. The hygiene of the stage is somewhat neglected, and the amount of illness among the employés, especially in the provinces, is particularly heavy. We are all concerned in improvements which make the theatre warm and wholesome and airy for the audience, but we are apt to forget that the producers of our entertainment have arduous work to do, often in a very unsatisfactory environment. We are glad to congratulate the management of Drury Lane Theatre on taking steps to render life behind the curtain a little less arduous and dangerous.

SIR WILLIAM BROADBENT ON THE PREVENTION OF TUBERCULOSIS.

THE admirable address of Sir William Broadbent on the Prevention of Tuberculosis delivered at Huddersfield upon the occasion of the opening of the magnificent new hospital for infectious diseases in that town will very possibly appear—as he himself allowed—to medical men to tell them nothing new. Although addressed to a lay audience in the main it is printed in our columns in full by our own special request, for it contains so much sound sense and so many points which although perfectly well known to every medical man are not sufficiently insisted on, that we consider that it will be of value to those members of the profession who did not hear it delivered to have a chance of reading it. For who are or ought to be the advisers and teachers of the public on this important question? Surely the family practitioners. It is their duty to point out the ways in which the scourge of "consumption" can be abated and as an additional incentive to do good they can refer their patients to Sir William Broadbent's weighty and yet perfectly simple words. In insisting upon the value of air Sir William Broadbent emphasised the necessity of open windows. Now, this may be possible in Huddersfield, but it is impossible to sleep and quite impossible to do any work in many parts of London with an open window, on account of the abominable and perfectly unnecessary noises.

Digitized by Google

The prevention of these is a work which the National Society for the Prevention of Tuberculosis might well take up. Apart from this, though, a good deal is being done. Enthusiastic landowners like Lord Vernon are alive to the necessity of reforming milk-supplies, and municipal bodies like those of Liverpool, Manchester, and London, are doing their best to overcome ignorance and prejudice in the matter of meat- and milk-supply. Huddersfield, we think, may be congratulated both upon its new hospital and upon the various gatherings connected with the opening thereof.

WOKING COTTAGE HOSPITAL.

THE local papers contain an account of a lengthy inquiry before Mr. G. F. Roumieu, coroner for West Surrey, as to the circumstances under which a man, who was removed to the Woking Cottage Hospital, came by his death on the railway after some dispute in the bar of the refreshment-room at the station. This account contains a statement which, so far as we remember, stands unique in the history of our cottage hospitals. It is stated that the coroner, having called before him the nurses from that institution, declined to allow them their expenses, expressed to them the very unsatisfactory nature of their evidence, and had to warn them, not only against similar behaviour in the future, but also against obstructing his officer when he went to them for the purpose of gathering evidence. We sincerely trust that the committee managing this cottage hospital will make a full inquiry into the matter and that both the inquiry and any decision which may be arrived at as the result of it will be as public as the condemnation of the coroner has been. It would be a serious thing if the public were led to believe that a staff maintained by their charitable gifts for the benefit of their fellow creatures could, under any circumstances, lend themselves, as is here implied, to defeat the administration of justice. The matter may admit of a complete explanation; if so, such explanation will doubtless be forthcoming.

THE ORDER OF ST. JOHN OF JERUSALEM.

AT the Camera Club, Charing-cross-road, on Oct. 20th, the Rev. W. K. R. Bedford, M.A., delivered a most entertaining address entitled, "The Knights Hospitallers: What They Did and What They are now Doing." Mr. Bedford, who is one of the chaplains to the Order of St. John of Jerusalem in England, has made a special study of the deeds of that religious and military Order in Malta and elsewhere, and on the present occasion occupied himself mainly with its history and development from its origin in Jerusalem as a charitable association between the years 1014 and 1023, through its subsequent successive settlements in Acre, Rhodes, and Malta, to its gradual decay and extinction in the beginning of the present century. These Knights Hospitallers or Knights of St. John succeeded to a considerable part of the possessions of the Knights Templars on the dissolution of the latter Order in 1312. After the plundering of the church of St. John in Malta by Napoleon in 1798, the Grand Master, Hompisch, took the precious relic, the hand of St. John, to St. Petersburg and created the Emperor Paul of Russia grand master of the Order. In the middle ages the Order was represented in England by the Priory of Clerkenwell, which existed almost contemporaneously with the First Crusade. During Wat Tyler's insurrection in 1376 much damage was done to the Priory as well as to the estates of the prior, who had a residence near Hampstead and a deer-park in the locality now known as St. John's Wood. The Priory was suppressed by Henry VIII. and entirely destroyed by the Protector Somerset in the reign of Edward VI. In 1834 steps were taken to establish an English branch of the Order, and in 1878 its great ambulance system was founded by two of the members—John Furley and Colonel Francis Duncan, R.E., St. John's Gate, Clerkenwell, being purchased for the Order about the same time by Sir Edmund Lechmere. The Queen granted a charter in 1888 and the insignia of the Order are worn at Court. Its operations include the ambulance work, the granting of medals to persons who save life at the risk of their own, and the maintenance of the Ophthalmic Hospital at Jerusalem, which has treated something like 50,000 patients. Mr. Bedford's remarks were illustrated by fifty photographic views and reproductions of old prints, shown with the fine electric-light lantern belonging to the club. It was announced that on Thursday, Nov. 3rd, at 8.15 P.M., Major Beevor, Royal Army Medical Corps, would deliver an address on the Afridi Campaign, illustrated with lantern slides.

TYPHOID ORCHITIS.

IN the *Journal des Praticiens* of Sept. 3rd Dr. Breton has related a case in which this rare complication occurred. Whilst convalescing from typhoid fever a youth, aged seventeen years, was attacked by pain in the right testicle which was soon followed by suppuration. When seen two months later there was ulceration of the skin of the scrotum to the extent of a franc piece and a small fistulous opening surrounded by a violaceous zone, the whole having the appearance of a tuberculous lesion. The testicle was invaded, but the epididymis was sound; there was swelling of the lymphatic glands in the corresponding groin. An injection of tuberculin gave no reaction. The whole of the suppurating area was removed; a bacteriological examination showed the presence of a bacillus with the characters of the typhoid bacillus, but the writer was not able to distinguish it absolutely from the colon bacillus. In eight days the wound was healed.

THE GARBAGE-MONGERS.

IT will be remembered that on Oct. 6th a man named Geary, trading as Ruffin and Co., was fined £100 including costs for being in possession of 44 barrels of stinking livers intended to be used in the form of meat extract as human food. Evidence was given that Geary was only performing experiments so as to make a meat extract which should command the market. On Oct. 20th Alfred Ashley was summoned as the vendor of the said livers. Ashley gave evidence and said that he did not know much about the livers. He got them through a shipping firm, Stahlschmidt and Co., who he believed got them from Munne and Schultze, of Hamburg, who got them from Buttle Bros., of Enniscorthy, Ireland. This modern commercial version of the House that Jack Built did not, however, satisfy the magistrate, who fined Ashley £25 and 5 guineas costs or three months' hard labour. Another man named Charles Sureties, who went by the name of Dr. Sureties and had formerly been manager to Geary, but carried on the trade of an extract blender in Bermondsey, was summoned on a similar charge. He did not attend the court and was fined £40 and 5 guineas costs, or three months' hard labour. No time would be allowed for grace. We consider that the law with regard to these sort of cases is in a most unsatisfactory condition. If Geary and Co. had put 2 grains of arsenic into their neighbours' beer they could every one have been sentenced to penal servitude. But because they prepare poison under the name of "table delicacies" or "meat extract" they get off with comparatively small fines. Actions such as this should be treated as attempted murder and in a case involving the possession, with intent to use or supply as food, of putrid aliments the offending party should be fed upon his own goods till they were finished, if

Digitized by Google

he lasted as long. He should be made to post at his own expense a notice of his conviction in every prominent newspaper in the kingdom and also in a prominent position in his shop and place of business. A second conviction should mean imprisonment for life. Except blackmailing there is no crime so mean and blackguardly as adulteration of food or selling putrid food. It should be put down with the heaviest possible hand.

PESTIS BUBONICA: PRECAUTIONS OF THE ITALIAN GOVERNMENT.

OUR Rome correspondent writes under date Oct. 25th: "The deaths, actual and threatened, from 'pestis bubonica' in the Viennese bacteriological laboratories, have caused the Italian Government to take all needful precautions against the introduction of the malady into the kingdom. The strictest hygienic surveillance is already established along the frontiers which divide the two countries; and this, working in harmony with the energetic measures enforced by the Austrian Government to isolate the 'pestis,' can hardly fail to confine the outbreak to its 'point of origin.' The 'Direzione della Sanità,' chiefly through the consular agencies of Italy, is in daily touch with the Viennese authorities; not only so, but within the Italian kingdom itself precautions of a like tenour with those at Vienna are being vigorously carried out. At Florence (as readers of THE LANCET are aware) Professor Lustig, who with three coadjutors of that school coöperated with Dr. Müller at Bombay in a series of studies on the 'pestis,' had established in the Tuscan capital a 'gabinetto batteriologico' for the further prosecution of these researches, and till the other day was engaged in experimenting on animals with his antitoxin. On the 23rd inst. the 'Consiglio Sanitario' of Tuscany, at an urgency meeting convened *ad hoc*, adopted measures identical with those devised by the central office in Rome and received from Professor Lustig, who was present and who requested to be heard, a spontaneous assurance that in presence of the danger he had, for the time at least, suspended all laboratory work in connexion with the 'pestis.'"

MASSAGE AND MOVEMENT IN INJURIES OF JOINTS.

IN many text-books of surgery the treatment which is still advocated for a sprain or dislocation is the fixation of the injured joint, and this treatment is usually based on the propositions, firstly, that fixation relieves the pain; secondly, that the rest prevents inflammation of the joint; and, thirdly, that it favours the repair of the ligaments. The stiffness which is so prone to follow any of these joint injuries is often very long-lasting and difficult to cure. Of late years there has arisen a tendency to treat sprains and luxations by more energetic methods, and a paper which sums up well the arguments in favour of the active treatment has recently appeared in *La Clinique*. It is by Dr. Lucien Tiberghien, of Brussels, and he points out that although rest relieves the pain the total amount of the suffering which has to be endured is by no means lessened, for the stiffness which succeeds is very painful to treat, while early and gentle massage, far from being painful, is very soothing. The stiffness resulting from injury to a joint is chiefly due to the organisation of the exudations which take place; these bind together the tendons and their sheaths, cause contraction of ligaments, and may even form adhesions between the articular surfaces; but if massage has been employed and early passive movement of the joint has been allowed the exuded materials, both leucocytes and serum, are carried off by the lymphatics and only sufficient is left to repair the damage which has been done. The degree and extent of the movement to be permitted vary somewhat with the joint affected and the extent of the lesion, but in all cases the ultimate result is that the articulation is freely and painlessly moveable in a much shorter time than if it has been kept carefully at rest.

THE WEST LONDON HOSPITAL.

H.R.H. PRINCESS LOUISE, MARCHIONESS OF LORNE, has intimated that she will attend at the West London Hospital on Wednesday, Dec. 7th, at 3 P.M., for the purpose of opening two of the three wards built in 1896. These two wards will be furnished with 52 beds, all of which have been generously presented, completely equipped, by friends of the institution, the Earl of Ilchester having given ten.

SCHOOL BOARDS AND THEIR MEDICAL OFFICERS.

A MEETING of the medical men of Halifax was held at the Halifax Club on Oct. 15th to consider the duties of the proposed school board medical officer for the borough. There was a large attendance, viz., Dr. Dolan, J.P., Dr. West Symes, Dr. Priestley Leech, Dr. Lockwood, Mr. Ellis, Mr. Kennedy, Dr. Finlayson, Dr. Marshall, Dr. Drury, Dr. Mantle, Mr. Macaulay, Mr. Woodyatt, Mr. Crowther, Mr. Shaw, Dr. Robertson, Dr. Knowles, Dr. Hunt, Mr. Morton, Mr. Branson, Dr. Bromley, Mr. Cookson, Mr. Whitcombe, Mr. Topham, Dr. Hue, and Dr. Dickson. Letters of apology were read from medical men who were unable to attend. The chair was taken by Dr. Dolan, and it was unanimously resolved that a deputation, consisting of Dr. Dolan, Dr. Mantle, and Mr. Ellis, should wait upon the School Board and represent that the profession did not approve of some of the proposed duties and should insist on the recognition by the board of all certificates of exemption and certificates for pupil teachers, whilst at the same time it should be made clear that the profession did not approve of the medical officers visiting school-children or teachers under the care of private practitioners. There was a strong expression of opinion as to the inadequacy of the salary, as pointed out by THE LANCET.[1] The deputation waited on the board on Oct. 17th with satisfactory results, and assurance was given that all certificates from private practitioners would be received as before.

THE OPEN-AIR TREATMENT OF TUBERCULOSIS FOR INFIRMARY PATIENTS.

DR. NATHAN RAW, the medical superintendent of the Mill-road Infirmary, Liverpool, has made a report to the committee of that institution in which briefly but clearly he states the case for the establishment of sanatoria for the treatment of cases of tuberculosis. After pointing out the extent to which tuberculosis prevails in closely peopled and ill-ventilated districts of large towns, and the diminution in the mortality from the disease *pari passu* with improvement in dwellings and other sanitary measures, inclusive of food-supply inspection, he gives a few figures from the records of the infirmary with which he is connected which show a gratifying diminution within the past few years; for whereas in 1893 the total number of patients suffering from tuberculosis admitted to the infirmary was 349, of whom 121 died, in 1897-98 there were but 195 admissions and 88 deaths. Dr. Raw explains the principle of the open-air treatment, which can, he says, be carried out in this country, thus obviating the necessity of sending tuberculous patients to seek sunshine and air in foreign lands. He thus enumerates the requisites of a sanatorium for the purpose of carrying out this treatment: "1. The building should be well arranged with a south aspect. 2. A dry, pure, well-

[1] THE LANCET, Oct. 1st, 1898, p. 886.

Digitized by Google

drained subsoil. 3. Pure atmosphere and abundance of sunlight. 4. A large garden or grounds well protected from wind. 5. Sheltered verandahs facing the sun. 6. Proper supervision." All these conditions are, he avers, to be found in the neighbourhood of Liverpool, and he confidently recommends the West Derby Board of Guardians to consider his suggestion to establish such an institution. Since only those in the early stages of the disease would be admissible for the treatment a building large enough to contain 30 or 40 patients, with a staff of 4 nurses and supervised by a visiting physician, would, he thinks, suffice to begin with. We trust that Dr. Raw's scheme will take practical shape and that we may have the pleasure of congratulating the West Derby Board of Guardians on being the first public body to take so wise a step towards the amelioration of the lot of a class of patients who form no small proportion of every Poor-law infirmary.

THE SOCIETY FOR THE PREVENTION OF CRUELTY TO CHILDREN.

MOST of our readers are acquainted with the duties discharged by the Society for the Prevention of Cruelty to Children. It is probable, however, that they realise only imperfectly the extension of the area over which those duties are exercised and the consequent effort and expense implied in that extension. Not even yet have all districts in this country been brought under the society's supervision, while the needs of our colonies, where nature is not all humane, are only now being discovered. The field already covered by the society is a wide one, but there is a wider one beyond it, and there is therefore a constant necessity for exertion. If we take the record for last August alone we find that it includes 2141 cases of proved cruelty. The great majority of these appear under the heading of "Neglect and starvation," though nearly 400 are instances of direct ill-treatment and assault. In other words, vice and poverty are the most fruitful sources of domestic tyranny. The method of treatment adopted by the society is commendably judicious. Though armed with the power of a punitive law a preference is given wherever possible to less heroic measures. Of the 2141 cases referred to 1675 were dismissed with a warning, but it is noteworthy that out of 258 prosecutions there were 248 convictions. These facts will suffice to prove to any who may still be doubtful as to the quality of the society's work that the judgment and activity which it exhibits are worthy of encouragement. Subscriptions to the funds of the society cannot all be large, but they can at least be regular, as is most important for the maintenance of this deserving work, and they are certain to be well applied.

THE FATE OF SUGARS SUBCUTANEOUSLY INJECTED.

AN article has been recently published in the *Archiv für Klinische Medicin* (Band 58, p. 523) by F. Voit on the Behaviour of Different Kinds of Sugar in Man after Subcutaneous Injection. By introducing them in this way into the economy the disturbing influence of digestion is abolished. Antiseptic precautions were of course taken and solutions of mono-, di-, and poly-saccharides were used and the urine was then examined both qualitatively and quantitatively for the sugar injected or for the presence of any other sugar. In the first instance 11·24, in the next 60, and in the third 100 grammes of grape sugar were injected in solutions containing 10 per cent. of the sugar. It was only in the third experiment that 2·64 grammes of the sugar were excreted by the urine, in the second experiment only traces of it, and in the first none at all. Similar large quantities of fruit sugar and of galactose were disposed of in the body, since after the injection of from 10·13 to 31·25 grammes of the former sugar only traces reappeared in the urine. Lastly, amongst the mono-saccharides the non-fermentable sugar sorbinose was tried with the result that after the subcutaneous injection of 10·15 grammes 3·7 grammes, or 36 per cent., reappeared in the urine. Of the pentoses there were examined arabinose, xylose, and rhamnose. Of the first two of these about one-half was disposed of in the body and of the rhamnose only about 14 per cent.; the remainder was eliminated unchanged. It was found that if these pentoses were ingested by the mouth a larger portion was disposed of and it is possible, Voit thinks, that it may be to some extent destroyed or altered in the stomach. Of the disaccharoses cane-sugar and milk-sugar were wholly and completely excreted as such by the kidneys; and since, when taken into the stomach, they are both used up to a greater or less extent, the conclusion is obvious that only the intestine is competent to effect their decomposition and render them serviceable. On the other hand, the third disaccharid, maltose, was completely disposed of when injected subcutaneously. Trehalose, which is isomeric with maltose, was only retained in the body to the extent of 85 per cent. These results agree well with those of E. Fischer on the action of blood-serum on the different kinds of sugars outside the body. They also show that the aldehyde nature of the different sugars does not form a measure of their destructibility, since milk sugar, in spite of its aldehyde nature, is not destroyed, whilst trehalose, which is not an aldehyde, is, and, further, that the greater or less facility of the breaking-up of a disaccharide does not coincide with corresponding behaviour in the body. Thus, cane sugar, which inverts easily, passes unchanged through the body, whilst the contrary holds for trehalose. Raffinose, which is a trisaccharide, was found in two experiments to be destroyed to about 35 per cent., whilst it is unaffected by blood-serum outside the body. The portion not destroyed reappeared in the urine as raffinose. Of the so-called polysaccharides glycogen was completely destroyed so that it did not reappear in the urine either as glycogen or as sugar. Achroödextrin, erythrodextrin, and amylodextrin (soluble starch) were used up in the body to the extent of about 75 per cent. of the quantity subcutaneously injected. Voit is of opinion that just as in Fischer's experiments outside the body in order to effect thorough fermentation of sugar, its antecedent splitting up into mono-saccharides is necessary, so the animal economy is not able to burn off the higher sugars until they have been broken up into their components.

MUNIFICENT GIFT TO WINSFORD.

CHESHIRE is to be congratulated on possessing a family with the benevolent traits of the Verdins, for it owes to the munificent spirit of this house many of its public buildings. Among the many gifts with which the name of Verdin is associated not one will be more useful or more appreciated than the new infirmary at Winsford, which was opened on Oct. 20th by the Duchess of Westminster. By the permission of the Queen the new infirmary, which was formerly the mansion of the Verdin family, is named after Prince Albert. It is a stone-fronted building standing on a site close to the station of the London and North-Western Railway Company. On the ground floor are reception, nurses', and convalescent rooms, and two men's wards with eight beds, whilst on the first floor are women's and children's wards which contain four beds. The building has been handsomely furnished by the donor, Mr. W. H. Verdin, D.L., J.P. Before presenting to Mr. Verdin the silver shield, which was meant as a recognition by the town of Middlewich of the gift of the infirmary, the Duke of Westminster said that "it would probably be within the recollection of many present

Digitized by Google

that he had already had the privilege of assisting in no less than three ceremonials, and his wife had taken part in another, which made four, in not much more than three years, to commemorate very noble work done in a very noble way by one or other of the Verdin family, who had done so much for that district and the adjoining district of Northwich. All their generous works would be a lasting benefit to their neighbours. Not only had they provided for the treatment of the mind of the inhabitants, but also for the cure and relief of suffering, whether from accident or disease." Mr. Verdin having replied, the Duchess of Westminster presented a portrait in oils of Mr. W. H. Verdin to his son, Lieutenant R. N. H. Verdin, Cheshire Yeomanry Cavalry, a gift from the inhabitants of Winsford to commemorate the attainment of Lieutenant Verdin's majority.

ABDOMINAL ADHESIONS AS A CAUSE OF PAIN.

IT was Mr. Mayo Robson, we believe, who first pointed out that many instances of severe abdominal pain spoken of as neuroses were due to adhesions and capable of cure by operation. These adhesions may affect the stomach, vermiform appendix, ovaries, Fallopian tubes, and omentum. One of the sequels of gastric ulcer is perigastritis, which may result in adhesions to the abdominal wall or other organs, forming sometimes a tumour which can be felt externally. In the *Boston Medical and Surgical Journal* of Sept. 29th Dr. J. C. Warren has published a case in which such adhesions were the cause of much suffering which was removed by operation. A man, aged forty-one years, who had suffered for years from dyspepsia and severe paroxysmal attacks of pain in the epigastrium, was admitted to hospital. He was sallow and emaciated. There was a tumour in the right hypochondrium, hard and ill-defined, and seemingly attached to the abdominal walls. An incision 5 in. long was made parallel to the right costal cartilages at a distance of about an inch. On dividing the abdominal parietes the liver was found attached to them by a thick exudation of lymph. The gall-bladder and the pylorus were buried in adhesions. After these had been broken down palpation failed to detect anything abnormal in the stomach or duodenum. The stomach was incised near the pylorus and explored. No ulcer or induration was felt in the stomach, but a cicatricial band narrowed the pylorus, so that only the forefinger could be pushed through; the opening was gradually stretched so as to admit the ring finger also. Complete recovery followed.

HYGIENE AND HEALTH IN HOT COUNTRIES.

DR. FEDERIES MONTALDO, who holds a commission in the medical department of the Spanish navy, has brought out a practical medical and hygienic guide for Europeans in hot climates, and according to a reviewer in the *Archives de Médecine Navale* for September it is a work which is entitled to very high commendation. In the first part the writer gives the intending traveller suitable advice as to his preparations prior to embarkation, entering into details regarding the composition of his baggage. Next, assuming that his European has made good his landing in some country within the tropics, he sketches out an ideal twenty-four hours as a model for his information and guidance, incidentally drawing his attention to his constant foes—to wit, heat, the sun, variations of temperature, moisture of the atmosphere, and what are somewhat vaguely called telluric miasmata. The important subject of diet is then dealt with, what to eat, drink, and avoid, the best time for meals, how to purify drinking water, the judicious use of alcoholic liquors, &c., the section ending with a chapter on the hygiene of clothing, inclusive of headgear, footgear, outside garments, underlinen, and bedding. The personal portion of his theme exhausted, Dr. Montaldo proceeds with a brief disquisition on organic diseases and their treatment, confining himself, it is said, to plainly worded description and practical advice. He approves of quinine for combating malaria and lays down rules for its employment, but he also vaunts the good qualities of calaya in similar cases, his experience on the west coast of Africa enabling him to recommend that drug with confidence. A summary of the symptoms and treatment of bites and stings follows, together with instructions for dealing with the common surgical affections, such as contusions, wounds, burns, fractures, and dislocations, the section concluding with hints as to the management of yellow fever, cholera, beri-beri, and other diseases usually met with inside tropical zones. Finally, the writer advises the European to seek his native clime without delay when he finds himself seriously weakened by anæmia or climatic cachexia, but at the same time he strongly recommends the establishment of sanatoria locally on the model of the institutions of this description which are to be found in English and French colonies. Dr. Montaldo, in the opinion of his friendly reviewer, writes with a facile pen and withal lucidly, avoiding technical terms so far as possible in order to make himself intelligible to non-professional readers. The Madrid Academy of Medicine has warmly commended his book, but it seems a pity it was not published a few years ago before the Cuban troubles began, for during that lamentable contest innumerable lives must have been lost for lack of sanitary knowledge.

SURGERY THEN AND NOW.

THE opening address at the Meath Hospital, Dublin, inaugurating the session of 1898-99, was delivered by Mr. Hepenstal Ormsby, surgeon to the hospital. After premising that it was almost impossible to get anything new about which to talk he said that he had made up his mind to take for his subject "A Century's Progress in Surgery." He reminded his hearers how in everything force had given place to gentleness. Especially was this marked in the treatment of dislocations. Patients were no longer bled wholesale, neither were they poisoned with mercury. But, great as these advances were, the two which shone out above all others were the introduction of anæsthetics and of antiseptics. Orthopædic surgery had made wonderful strides and so had the surgery of the brain. Mr. Ormsby referred to the multiplication of special hospitals and said that there was a danger lest practitioners should rather be led to make a diagnosis by the aid of various special methods of investigation without taking into consideration all the circumstances of the cases, as was the way, the necessary way, with the surgeons of a past generation who had to rely mainly on their unaided senses. He also alluded to the Vaccination Act and the improved status of the medical practitioner in the army. Perhaps in some of the advances to which he referred the pendulum has swung too much the other way, notably, as Mr. Ormsby remarked, in the practically total abolition of bleeding. This is a therapeutic measure which, wisely employed, is of incalculable service, though possibly more in medical cases—e.g., dilated right heart, pneumonia, and pleurisy—than in surgical cases, though in these latter the use of leeches to an acutely inflamed joint gives the greatest relief. But the horrors of hospitals of fifty years ago can be but faintly imagined by the practitioner of to-day, and, on the other hand, if Liston or Cooper could arise to-day and see a modern operation involving the abdominal or thoracic cavity or the removal of a cerebral tumour, what a perfect revelation it would be to them. And the beauty of all these advances is that they are the outcome, not of one or two men's brains, but of the laborious, patient work of hundreds of toilers; in the dissecting room, in the post-mortem room, in the laboratory, the anatomist,

Digitized by Google

the pathologist, and the physiologist wrest the secrets from nature. Slowly has the great house of knowledge been built up, rotten stones have been taken out and replaced by fresh and sound ones, portions pulled down and rebuilt, till at length what we do know stands upon enduring ground. At least, so it seems for the present, but there is still plenty for the science builders of to-day and the future to make plainer and to investigate.

THE SHEFFIELD SCHOOL OF MEDICINE.

THE opening of the seventy-first session of the Sheffield School of Medicine, which is a department of the University College, was marked by an address delivered by Dr. Dyson, the Vice-President of the College. Dr. Dyson really combined with his address a report upon the progress of the school. He pointed out that the school had certain most salutary regulations, one of which was that a student was bound to present himself for an examination within six months after that examination became due. This did away with "chronics." A very fair percentage—namely, 12—of their students went for a university degree, a percentage which compared favourably with the larger and richer schools. He might mention that smaller schools had advantages over large in that their students got more individual attention. The equipment of the school had recently been greatly improved owing to the generosity of Sheffield citizens. The chair of physiology was still in need of an endowment. Passing to more purely professional matters Dr. Dyson referred to the new Vaccination Act, saying that although the Royal Colleges of Physicians and Surgeons had unanimously sent in their opinion as to the value of vaccination, yet the new Bill had been passed. As regarded the providing of a standardised lymph and increased facilities for supply it was a good Bill. He had seen two epidemics of small-pox and did not want to see another, but if one did come and the fatuous conscience clause was taken advantage of by many, after that—the deluge. After mentioning the action of the General Medical Council as to unqualified assistants and congratulating the profession upon the establishment of the Royal Army Medical Corps Dr. Dyson passed on to consider the movement in connexion with the prevention of tuberculosis. They might, he thought, try the open-air treatment, not, indeed, in Sheffield itself, but on the moors, which were quite close to the city. After the conclusion of the address the various prizes and certificates were presented. Dr. Dyson's address is particularly interesting as showing how much better off in one way the provincial medical schools are than those in London—namely, in the benefactions which they receive from citizens.

THE PATHOLOGY OF DENTAL CYSTS.

SOME valuable light is thrown on the pathology of dental cysts in an interesting communication to the October issue of the *Journal of the British Dental Association*. The author, Mr. J. G. Turner, draws his conclusions from an exhaustive microscopical examination of 17 cases which have been under his care. In all with the exception of one he was able to discover a distinct epithelial lining, and from the specimens obtained he was able to demonstrate the succession of changes which occur in the development of these cysts. The nucleus of origin for these cysts is to be found in the epithelial remnants so frequently met with in the alveolar dental ligament. These masses were first demonstrated by Malassiez under the name of para-dental epithelial remnants, and have their origin, according to that observer, in a prolongation of the enamel-forming organ of the tooth which precedes and determines the formation and shape of the dentine of the root and is known as the epithelial sheath of Hertwig. On the formation of the dentine the surrounding mesoblastic cells invade and partly destroy this sheath, applying themselves to the surface of the dentine and forming the cementum and alveolar dental ligament, the undestroyed portions of the sheath remaining as the para-dental epithelial remnants. Through the continuous absorption of small quantities of septic matter an active growth is induced in these remnants, so that either a solid epithelial mass or an epithelial reticulum enclosing islands containing cells of mesoblastic origin is formed. That the septic matter is the product of putrefactive changes in the pulp of a tooth or teeth is pretty clearly demonstrated by the fact that in 27 cysts all were connected with teeth containing septic pulps. These reticula or masses, although present in chronically thickened alveolar ligament, are more constant in the small growths attached to septic roots known as root tumours and frequently form the chief element. These epithelial root tumours are of common occurrence and when of any size determine for themselves a connective tissue capsule. By a continued growth at the periphery of these epithelial masses or reticula and a degeneration in the centre a small cyst is in time formed containing a pultaceous mass like inspissated pus. At some period the contents liquefy, and with the continued growth of the epithelium a clinically recognisable cyst is formed. These stages are all very clearly shown in the paper by means of admirable photo-micrographs. The paper also contains details of three cases of gingival cysts. Such growths possibly have their origin in those clusters of epithelium constantly met with in the muco-periosteum of the gums under the term "glands of Serres," and judging from the cases recorded the irritant which lights up activity in these masses is to be found in the septic matter absorbed from a sinus in connexion with a pulpless tooth. These cysts—namely, dental and gingival—are interesting, too, as examples of tumour production, the cause and effect being so clearly demonstrable. In the para-dental epithelial remnants and the glands of Serres we have the "rests," in the absorbed septic matter the probable chronic irritant, and in the epithelial cyst, dental or gingival, the result.

THE WATER-SUPPLY OF LEICESTER.

IT has been suggested in regard to the proposal to derive a new source of water-supply for Leicester from the upper reaches of the Derwent in Derbyshire that there would be a possibility of introducing water which would induce the disease known as goitre. As is well known, "Derbyshire neck" is constantly prevalent in certain parts of Derbyshire, and appears to be traceable to the drinking of water which is rich in salts of lime and magnesia. The actual predisposing cause of this disease is surrounded with considerable obscurity. Instances have been placed on record in which, on the contrary, soft water would appear to have produced the disease. In the Himalayas in India, for example, goitre occurs where snow water is drunk. On the other hand, the balance of evidence certainly favours the view that goitre prevails most where the water-supply is derived from limestone rocks. This is, at any rate, the character of the water supplied in many parts of Derbyshire, where the disease has been so pronounced as to have given it the name of "Derbyshire neck." The municipal authorities have therefore very properly caused an inquiry to be made on this point into the character and quality of the water which it is proposed to draw from the upper waters of the Derwent. It is important that such an inquiry should be very carefully conducted before the new supply becomes available. Dr. J. H. Davies has been instrumental in drawing attention to the subject and last week the views of Sir Edward Frankland were placed before the water committee. In his report Sir Edward Frankland points out that the districts in Derbyshire which suffer from this

Digitized by Google

disease are situated upon the coal measures, which impart to the water flowing over them or percolating through them an extreme degree of hardness caused by the solution of salts of lime and magnesia. On the other hand, the contemplated supply from the upper reaches of the Derwent, besides possessing an extremely high degree of organic purity, is remarkably soft, being almost absolutely free from salts of lime and magnesia. This water is supplied to Manchester, Macclesfield, and Buxton, and is free from reproach. It is said that goitre is at present not unknown in Leicester and Sir Edward Frankland concludes that so far from the disease being increased by the introduction of the pure and soft water of the Derwent the hope may be entertained that by the use of a water having only one-seventh of the hardness of the present supply the disease in the town may be entirely extinguished.

ISOLATION HOSPITALS.

AN important and animated discussion recently occurred at a meeting of the Lincoln Board of Guardians. Lincoln seems to be very much behind the times, inasmuch as there is no isolation hospital there for infectious cases. But cases have recently appeared in the town which demonstrate the need for such an institution. A man employed at a brick-yard at 21*s.* a week had six children, five of whom had been attacked about a week before the discussion took place with scarlet fever. They were attended by a private medical man at their home, but subsequently the relieving officer gave an order for them to be treated by the same medical man, he to act as if he was the district medical officer. The mother of the children was about to be confined, and it was represented to the clerk to the board of guardians that it would be exceedingly dangerous for her to be confined in a house where children were suffering from scarlet fever, and after a consultation between the clerk and the urban sanitary authorities the mother was removed to the fever ward of the workhouse to be confined. A long discussion then took place on the question—Whose duty was it to provide isolation for the children? The board of guardians rightly repudiated any legal responsibility, but a few of the members thought it would be an act of charity to remove the children to the workhouse; a proposal, however, to this effect was lost by a large majority. The urban sanitary authorities alleged that though they had the power to build an isolation hospital it was not their duty. We agree with the remarks of the clerk to the guardians that the onus of dealing with it does rest upon the sanitary authority of the district. The importance of an isolation hospital cannot be exaggerated. In many houses, such as the one in this case, proper isolation cannot be carried out; the inhabitants are not paupers and yet have not sufficient means to adopt the necessary precautions against the disease spreading to other houses. In the case just related it had already attacked patients in the adjoining house. If an extensive epidemic occurs in that district the urban sanitary authority will be distinctly to blame, and immediate steps should be taken to establish an isolation hospital to which similar cases might be removed.

DEATH UNDER CHLOROFORM.

WE have received, through the courtesy of Mr. Lewis Buck, resident medical officer to the Bolton Union Workhouse, very careful notes of a fatality under chloroform which occurred recently at that institution. The patient, a weaver, aged sixty-six years, suffered from epithelioma affecting the larynx. He showed some signs of senile change and had pulmonary emphysema, dilated hypertrophied heart, and diseased arteries. There was no physical evidence of fatty heart, but there was a marked history of excessive indulgence in alcohol. There was considerable narrowing of the larynx leading to dyspnœa, for which the operation was imperative. The patient was given the A.C.E. mixture, but as the ether which it contained appeared to irritate the air-passages chloroform was substituted, being given by dropping it upon a single layer of a towel placed over the patient's mouth and nose. He took the anæsthetic badly and a quarter of an hour after the commencement of the administration of the anæsthetic he died. There was apparently no failure of the heart, as evidence of circulation existed after respiration had quite ceased. Air could by artificial respiration be made to enter the lungs freely. There was no shock, as no operation was commenced. The reflexes were not abolished when dangerous symptoms appeared. The administrator was a careful and experienced man, who believed that no "overdose" in the usual acceptation of the phrase occurred. The death was sudden and very little chloroform had been given. The death appears to have been due to respiratory failure brought about by what, under ordinary circumstances, would have proved a non-poisonous dose. In cases of chronic dyspnœa, especially in alcoholic subjects, there is usually a gradual carbonisation of the blood which renders such patients peculiarly bad subjects for anæsthetics. We are not told whether cyanosis was a prominent symptom in the present case; as a rule it exists and renders the task of the anæsthetist a doubly difficult one, as he has to steer safely between the Scylla of overdosage—a very variable and often a very narrow margin existing between safety and danger—and the Charybdis of insufficient narcosis marked by obstreperous and perilous excitement. In suitable cases there is no doubt that Schleich's infiltration method offers a satisfactory alternative to general anæsthesia. In connexion with the statement that circulation appeared to persist after respiratory failure it is important to note that McKendrick and other physiologists have maintained that although the heart may appear to be beating it is in these cases not beating effectively, and circulation is not, in fact, taking place, although cardiac movements may be easily felt and seen.

THE Council of the Childhood Society, which was established for the scientific study of the mental and physical conditions of children, announces a course of lectures to be given in the library of the Sanitary Institute, 72, Margaret-street, W., on Oct. 27th and following Thursdays up to Dec. 8th inclusive, at 8 P.M. Dr. Symes Thompson will lecture on Nov. 24th, his subject being Mute Children, their Education and Health Care, and on Dec. 8th Dr. Henry Rayner will lecture upon the Early Recognition and Treatment of Mental Condition. Children, perhaps, are too often misunderstood, so that this society does a good work in trying to obviate the tendencies to such misunderstandings.

THE second trial of John Lloyd Whitmarsh upon the charge of the wilful murder of Alice Bayly, who died, according to the prosecution, as a result of an attempt to produce criminal abortion, was concluded on Wednesday night when the jury returned a verdict of guilty, qualified with "the strongest possible" recommendation to mercy. Mr. Justice Bigham pronounced sentence of death, informing the prisoner at the same time that the recommendation of the jury would be forwarded to the proper quarter and that he would support it with everything that he could say properly.

DR. SIDNEY COUPLAND has been appointed a Commissioner of Lunacy in the room of Dr. Reginald Southey, resigned. We congratulate Dr. Coupland on his appointment very heartily. He has been our colleague in the editorial duties

Digitized by Google

of THE LANCET for many years, and we are aware that the confidence thus shown in his judgment and capacity for work is thoroughly justified, while his all-round attainments as a practical and scientific physician, no less than his labours in behalf of the recent Royal Commission on Vaccination, selected him clearly for official recognition.

A MONUMENT in honour of Dr. Hans Wilhelm Meyer, whose name is known so well in connexion with adenoid growths of the pharynx, was unveiled on Wednesday last at Copenhagen. We hope to give next week an account of the proceedings. Sir Felix Semon made over the memorial to the municipality of Copenhagen on behalf of the international committee which organised the movement.

THE annual distribution of prizes at the St. George's Hospital Medical School will take place in the board room of the hospital to-day (Saturday) at 2.30 P.M. The distribution will be made by His Grace the Duke of Westminster, K.G., joint treasurer with Mr. Holmes.

MR. R. H. P. CRAWFURD, M.D. Oxon., M.R.C.P. Lond., has been appointed assistant physician to King's College Hospital.

REPORT OF THE SANITARY COMMISSIONER WITH THE GOVERNMENT OF INDIA FOR THE YEAR 1896.[1]

CONCLUDING NOTICE.[2]

IN continuation of our remarks regarding hepatic abscess we may add that, according to a table in the report under review, the mortality from abscess of the liver in 1896 was 17 times greater among European than among native soldiers, and it is stated to have been 70 times greater in the previous year. The admission ratio from dysentery, on the other hand, among European soldiers was rather less than that of native soldiers, 1 : 1·5.

So much attention has of late been given to the subject of venereal diseases among British troops serving in India that this matter need not now detain us. It may suffice to say that the secondary syphilis ratio of 1896 is about the highest on record.

Turning to the vital statistics of officers serving in India we find that the death-rate in 1896 for those of the British army was 14·18 and for the Indian army 10·76 per 1000 respectively. The number of deaths from enteric fever among both British and Indian officers was the same as in 1895. The number of fatal cases from this disease is usually greater among the British than among the Indian officers, apparently because the latter have to serve first with British regiments, and it is known that youthful and recently arrived men are more liable to be attacked than others.

Turning now to the next section of the report—that on the native army of India—we find, as might be expected, that ague was the chief cause of admission—36 per cent. of the total admissions. The chief causes of death among soldiers of the native army were pneumonia and remittent fever, the former causing 31 per cent. and the latter 10 per cent. of the total deaths. The mortality-rate in the native army in 1896, including absent deaths, was altogether 12·57 per 1000, as against 15·71 in the preceding year. The smaller sickness and mortality in 1896 is attributed by the Sanitary Commissioner to the dry and non-malarious character of the year; there were, however, more influenza and cholera in 1896. It may be briefly said that while the young soldiers of the British army die from enteric fever the chief causes of death in the native army are respiratory diseases. In 1896 over 36 per cent. of all the deaths were due to these diseases.

Scurvy seems to be unduly prevalent among the native troops, and the existing amount of that disease is alleged to be greater than that actually returned and it is believed to underlie a vast amount of sickness which does not directly bear its name. Hepatic abscess, as has been already said, is not a frequent disease of the native soldier, and this probably points to the injurious influence of a too liberal use of alcohol and animal food on the part of the European in a hot climate like that of India. Touching venereal disease it may be mentioned that there were only 37 admissions for every 1000 men among native troops, as against 512 for every 1000 men among European troops. Several reasons have been urged in explamation of this striking difference, into which it is needless, however, to enter on the present occasion.

Section IV. of the Sanitary Commissioner's report deals with the Jails of India. The year 1896 having been comparatively settled, rainless, and bright, sickness—especially sickness attributable to malaria—was, we are told, less than usual, but there was more or less food scarcity and influenza and cholera were somewhat more prevalent. The ratios of admissions into hospital and of constantly sick indicate that the year was a comparatively healthy one. The presence of famine in India (as in the Central Provinces especially) sends numbers of unfortunate natives into jails. The enfeebled state of their health makes them, of course, less resistant to disease. Overcrowding, too, existed in some of the jails. The chief causes of death were dysentery, pneumonia, tubercle of the lungs, and diarrhœa. Dysentery gave rise to 21 per cent. of the total deaths, pneumonia to 16 per cent., and pulmonary tubercle, to 11 per cent.

In respect of cholera in the jail population 1896 compares on the whole favourably with preceding years. July and August were the worst months for cholera. The high rate of mortality from bowel complaints in the native jail population as compared with that in the European and native armies is a notable feature. As regards respiratory diseases, again, taking the mortality of European troops as 1, that of the native troops is 4·8 and that of the prisoners is 6·9. This seems to indicate that while a previous medical history of malaria renders the individual very vulnerable to causes of acute pulmonary disease, and insufficient clothing is also a factor, the overcrowding and defective ventilation of buildings occupied by persons living in community have likewise a very important bearing in the production of pneumonia and affections of the respiratory organs.

Section V. deals with the Vital Statistics of the General Population and Section VI. with the History of the Chief Diseases. The subject of cholera and the modern bacteriological researches in relation to it, together with the late experiments in cholera prophylaxis and the distribution of the disease in India, are pretty freely discussed, and this portion of the report, we may add, will well repay perusal and consideration. The appearance of bubonic plague in Bombay in the latter part of 1896, the fevers of India and Assam, *Kala azar*, and other matters of medical and epidemiological interest are also dealt with. In conclusion, we may say that we consider the Report for 1896 of the Sanitary Commissioner with the Government of India an admirably compiled as well as an interesting official production.

[1] Annual Report of the Sanitary Commissioner with the Government of India, 1896, with Appendices and Returns of Sickness and Mortality among European Troops and Prisoners in India for the Year. Calcutta: Office of the Superintendent of Government Printing, India. 1898. Price, 5 rupees.

[2] The First and Second Notices appeared in THE LANCET of Sept. 24th and Oct. 8th, 1898, respectively.

HOSPITAL ABUSE AT COVENTRY.

THE question of hospital abuse at Coventry has now reached a new stage. The article by our Special Commissioner published in THE LANCET of April 17th, 1897, set out very clearly the condition of things and showed that the essential point in the whole matter was the influence and control of the working men upon the funds and management of the hospital. The workmen subscribe 1*d.* per week and the sums raised in this manner have increased from £132 in 1874 to £1300 in 1896, while voluntary subscriptions and donations are declining. This 1*d.* per week subscription though nominally voluntary is practically a compulsory tax. The result, to put it shortly, is that every workman expects that he has a right to treatment at the hospital for as long as he likes in return for his 1*d.* per week. Early in this year a sub-committee was appointed by the general committee to

Digitized by Google

inquire into the matter. This sub-committee brought up a report in May which was referred back, and finally the amended report came up on Oct. 12th. The report as printed in the *Coventry Herald* was as follows:—

The sub-committee ascertained from the representatives of the working men's committee that the answers to the questions which were previously submitted to them were given somewhat under a misapprehension and amended answers to Questions 1 and 3 have now been given. The questions with the original and amended answers are as follows:—

Question.—1. If a man who subscribes to the Hospital Saturday Fund and earning, say, £3 or £4 per week, applied for a ticket from his works, would he be granted one?

Answer.—No answer could be given.

Amended answer.—No.

Question.—3. The sub-committee suggest making inquiries as to the position of candidates (say for one month) who it is considered can well afford to pay a medical man, and ask if the members of the Hospital Saturday Committee are willing to assist them in obtaining the necessary information.

Answer.—They could not entertain the suggestion.

Amended Answer.—The matter will now be taken in hand and inquiries made as suggested in the question.

Following up the undertaking given by them, the working men's committee have held an inquiry and investigated all the out-patient cases treated at the hospital between May 21st and June 30th, and have submitted a report thereon to your sub-committee.

During the period investigated by the working man's committee the number of out-patients treated was as follows:—By ticket, 70; without ticket, 126. Special departments: by ticket, 37; without ticket, 27. From the report it would appear that 30 cases were kept back for strict inquiry which upon investigation it was thought would probably be found to be instances of hospital abuse. The cases were reported upon by various members of the committee, and only 2 cases were discovered which, in the opinion of the working men's committee, were such as should not have been treated at the hospital. The sub-committee do not consider the report of the working men's committee as regards the abuse to be conclusive, as it must be admitted that in many cases the patients were in receipt of wages sufficient to enable them to pay to a dispensary, a medical service, or a club. This view has been expressed and upheld by the honorary medical staff, who from their position are well able to judge as to the suitability of the cases which come before them for hospital treatment.

With reference to the cases treated without a ticket, the sub-committee believe that a very large proportion of those patients could have obtained a ticket if they had thought proper to have taken the trouble to do so, and having regard to this fact the sub-committee recommend: "That on and after 1st November next every patient be required to present a ticket before receiving treatment, excepting in the case of simple teeth extractions for children under twelve, accidents, and such acute medical cases as require immediate help, and as to the latter cases after first aid they should be required to obtain the necessary tickets for subsequent treatment."

The sub-committee have revised the existing ticket and recommend that the ticket as revised should be brought into use concurrently with the previous recommendation. The sub-committee believe that the strict enforcement of the ticket system will be productive of great good to the hospital by causing its benefits to be more strictly confined to deserving cases. It is hoped that the subscribers, the managers of workshops and of the philanthropic institutions, and all who have tickets at their disposal will do all in their power to carry out the instructions and regulations on the tickets.

The chairman moved the adoption of the report, which motion was eventually carried. It will be seen from the report that a revised ticket is to be issued, and those who give away the tickets are to be requested to see that they only select fit objects for charitable relief. The medical staff as a whole appear to incline to the belief that the ticket system is a wrong one. This is certainly our own opinion, for in general for one subscriber who looks after the proper distribution of his or her tickets there are fifty who do not. Even if this system were to be altogether done away with there remains the question of the right of workmen to hospital relief, however high their wages, on account of the 1*d.* per week subscription. So there appears to exist this dilemma. If the 1*d.* per week is to be, as it should be, looked upon as a mere subscription and not as entitling the giver of necessity to relief, the Saturday collections will diminish very greatly. If it is to be looked upon as entitling the givers to treatment as in a provident dispensary, then the medical staff of the hospital will have to be paid and in that case the appointment of hospital surgeon or physician should be open to every medical man in the town simply on account of his being a practising medical man in Coventry.

THE ENTRIES AT THE MEDICAL SCHOOLS.

THE following table, the figures of which have been supplied to us by the courtesy of the deans of the various schools and medical faculties, will give some idea of the number of students who have decided to enter the medical profession this year. The first column of the table is that to which particular attention should be directed as it shows the number of students who have entered for the full course of medical study. The other columns are of interest, and especially that relating to dental students, but the gross totals both for the present and past medical sessions only tend to show the relative popularity of the various schools. It should be pointed out that last year's totals at King's College and the London School of Medicine for Women show the total number of full students only. With regard to St. George's Medical School the figures do not include students who have entered for a course of tropical medicine. Under the agreement whereby joint cards of admission are issued to the clinical instruction of the following hospitals and schools of medicine—viz., Charing-cross, Guy's, King's College, Middlesex, St. George's, St. Mary's, St. Thomas's, University College, and Westminster—42 qualified men have entered since the 1st of May of this year—that is to say, 15 from the United Kingdom, 12 from the colonies, and 15 from foreign countries. These figures, which belong to the "special courses" column of the table, cannot, of course, be placed against the name of any one school. They should, however, be taken note of in making comparisons.

ENTRIES FOR THE YEAR 1898-99.

Name of Medical School.	Full students.	Special courses.	Prel. sci.	Dental.	Total.	Total 1897-98.

University College of South Wales and Monmouthshire, Cardiff, sent in their figures too late to be included in the above table. Those figures are as follows: Full students, 15; special course students, 4; prelim. sci. students, 13—total 32.

NEW INFECTIOUS DISEASES SANATORIUM AT HUDDERSFIELD.

TWENTY years ago the Huddersfield Corporation began to exercise the powers they had obtained for the establishment of an infectious diseases hospital. On Jan. 1st, 1878, 15 cases were under treatment and 163 patients passed through the hospital during that year. During 1897 the number of patients under treatment reached 700. The progressive demands upon the resources of an inadequate and out-of-date building have led to the erection of a "sanatorium," which was formally opened by Sir William Broadbent, himself a native of Huddersfield, on Oct. 22nd.

The sanatorium has been built from the plans of Messrs. Edward Thomas and Sons, Queen Anne's-gate, S.W., in competition with 144 other architects. An examination of the hospital is alone necessary to confirm the encomiums of Sir William Broadbent when he said at the opening ceremony that everything connected with it met with his entire approval. The plan may be concisely described as a long

Digitized by Google

open corridor, at one end of which is the handsome administrative block of three storeys, in the Renaissance style, at the other the buildings for the laundry, the disinfecting apparatus, and mortuary. In the intervening space, on each side of the central corridor, stand the ward pavilions. The pavilions stand on pillars, are one storey high, and a branch from the main corridor enters the middle of each transversely. The ward kitchen immediately confronts the visitor with a ward of fourteen beds on each side. The pavilions run N.N.E. by S.S.W. A small rectangular block stands out from the western aspect of the end of each and contains the bathrooms and lavatories, whilst from the centre of the eastern side a ward of two beds communicating with the large ward has been projected. The cubic space to each bed in these small wards is 2155 cubic feet; in the large wards 2095 cubic feet. The pavilions are bright and cheerful, there is a window between each bed, whilst the direction of the pavilions ensures a maximum of sunshine. The floors are fireproof covered with polished teak laid diagonally; all corners and angles have been rounded; the walls are in Keene's cement painted and varnished; the windows are on the N.A.P. principle and can be cleaned from the outside; and all the pipes, electric wires, and flushing cisterns are in the false roof where they are accessible from the outside. The heating is partly by radiators and hot-water pipes and partly by open fireplaces. A ventilating stove with an ugly black flue in the centre of the ward would spoil the appearance of the ward less if its funereal colour were changed to a bright, cheerful tint. With the exception of a small fan in one of the walls of each large ward there is no attempt to change the air of the ward by mechanical means. Under each bed is an inlet for fresh air, and in the wall above the beds are the apertures leading to circular outlet shafts discharging on the eaves, whilst Boyle's ventilators are placed on the ridge and communicate with the highest point of the ceilings. The beds are Gale's iron bedsteads, fitted with Lawson Tait mattresses, upon which a mattress of white horsehair is placed. The kitchens and lavatories are fitted with every modern requisite, and an ingenious shelved cupboard, closed with an air-tight sheet-iron door but projecting into the open-air, to which its sides are open by lowered ventilators, deserves mention. It is intended for the storage of chamber utensils the contents of which it is desirable to keep for subsequent examination. The floors of the kitchen and lavatories are in Terrazo pavement, the walls in glazed bricks, so that all may be washed down with the hose-pipe. The complete scheme comprises five pavilions. Three only have been erected. These, with the isolation block of ten beds, in course of erection, provide 100 beds.

The quarters for the medical officer, matron, nurses, and servants are excellent. Bright pictures and excellent furnishings adorn the sitting-rooms and the bedroom appointments are marked by taste and comfort. The kitchens and stores are in a separate block immediately behind the administrative block, whilst between the kitchen and ward pavilions intervenes the receiving block, consisting of a verandah-protected room, opening at once into a bathroom and thence into the central corridor. On the other side of the corridor is the discharge block, similar in its arrangements to the receiving block. The site is about 12 acres in extent, and together with the 71 ft. between each pavilion is being laid out as a recreation ground for convalescent patients. Exclusive of the land the sanatorium has cost £24,667, and the total of the contracts is about £30,000. It is a modern hospital of the best type and will prove a valuable help to the corporation in checking epidemics and safeguarding the health of the town. By adding a laboratory for serum diagnosis and the bacteriological examination of diphtheritic or suspected diphtheritic membrane and the appointment of a resident medical officer capable of making use of such a laboratory the corporation would give completeness to a scheme in which nothing that could add to the welfare of the sick seems to have been overlooked.

Sir WILLIAM BROADBENT, in reply to a graceful little speech by the Mayor on presenting a gold key of the building, after tending his thanks for the honour done to him that day, referred to the fact that Huddersfield was the very first town to adopt the compulsory Notification Act. He mentioned that because notification was a subject which he had deeply at heart and for advocating which he had at one time incurred great unpopularity. He then declared the building open. In the afternoon Sir William Broadbent delivered his address in the lecture hall at the Technical College upon "The Prevention of Consumption and other Forms of Tuberculosis." This address will be found in full in another column. The audience comprised both medical men and laymen and the address was listened to with marked attention. In the evening there was a banquet at which Sir William Broadbent, in returning thanks for the toast of "The Medical Profession," remarked upon the enormous progress made in medical matters from comparative darkness into light.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN thirty-three of the largest English towns 6217 births and 4043 deaths were registered during the week ending Oct. 22nd. The annual rate of mortality in these towns, which had declined in the six preceding weeks from 24·6 to 19·0 per 1000, further fell last week to 18·8. In London the rate was 17·3 per 1000, while it averaged 19·8 in the thirty-two provincial towns. The lowest death-rates in these towns were 11·4 in Cardiff, 11·7 in Huddersfield, 12·5 in Blackburn, and 12·8 in Bristol; the highest rates were 24·4 in Liverpool, 25·7 in Sunderland, 26·4 in Newcastle-upon-Tyne, and 30·2 in Salford. The 4043 deaths in these towns included 538 which were referred to the principal zymotic diseases, against 774 and 618 in the two preceding weeks; of these, 250 resulted from diarrhœa, 100 from "fever" (principally enteric), 72 from diphtheria, 48 from measles, 36 from whooping-cough, and 32 from scarlet fever. The lowest death-rates from these diseases were recorded in Croydon, Cardiff, Wolverhampton, and Bradford; and the highest rates in Norwich, Salford, Hull, and Sunderland. The greatest mortality from measles occurred in Plymouth, Norwich, and Gateshead; from "fever" in Nottingham, Salford, Halifax, Leeds, Hull, and Sunderland; and from diarrhœa in West Ham, Burnley, Salford, Hull, and Sunderland. The mortality from scarlet fever and from whooping-cough showed no marked excess in any of the large towns. The 72 deaths from diphtheria included 30 in London, 6 in Swansea, 6 in Sheffield, 5 in Portsmouth, 5 in Liverpool, 4 in Leicester, and 3 in West Ham. No fatal case of small-pox was registered last week in any of the thirty-three large towns, and no small-pox patients were under treatment in any of the Metropolitan Asylum Hospitals. The number of scarlet fever patients in these hospitals and in the London Fever Hospital on Saturday last, Oct. 22nd, was 2915, against 2459, 2606, and 2728 at the end of the three preceding weeks; 381 new cases were admitted during the week, against 300, 358, and 357 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 226 and 263 in the two preceding weeks, were again 263 last week, and were 35 below the corrected average. The causes of 43, or 1·1 per cent., of the deaths in the thirty-three towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Bristol, Nottingham, Bradford, Leeds, and in fourteen other smaller towns; the largest proportions of uncertified deaths were registered in West Ham, Leicester, Liverpool, and Preston.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had increased in the three preceding weeks from 19·1 to 20·7 per 1000, declined again to 19·0 during the week ending Oct. 22nd, but slightly exceeded the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 13·0 in Leith and 13·7 in Aberdeen to 22·1 in Perth and 23·8 in Greenock. The 572 deaths in these towns included 38 which were referred to diarrhœa, 19 to whooping-cough, 9 to "fever," 8 to measles, 6 to scarlet fever, and 6 to diphtheria. In all, 86 deaths resulted from these principal zymotic diseases, against 123 and 105 in the two preceding weeks. These 86 deaths were equal to an annual rate of 2·9 per 1000, which was 0·4 above the mean rate last week from the same diseases in the thirty-three large English towns. The 38 fatal cases of diarrhœa showed a further decline from those recorded in recent weeks, and included 18 in Glasgow and 9 in Dundee. The 19 deaths from whooping-cough corresponded with the number in each of the two

Digitized by Google

preceding weeks, and included 11 in Glasgow and 3 in Edinburgh. The deaths referred to different forms of "fever," which had been 14 and 12 in the two preceding weeks, further declined to 9 last week, of which 5 occurred in Glasgow and 4 in Greenock. Of the 8 fatal cases of measles 5 were recorded in Edinburgh and 3 in Glasgow. The deaths from diphtheria, which had been 7 and 8 in the two preceding weeks, declined again to 6 last week, and included 2 in Glasgow, 2 in Edinburgh, and 2 in Dundee. Of the 6 fatal cases of scarlet-fever, 3 occurred in Glasgow and 3 in Edinburgh. The deaths referred to diseases of the respiratory organs in these towns, which had been 105 and 141 in the two preceding weeks, declined to 120 last week, and were 24 below the number in the corresponding period of last year. The causes of 32, or nearly 6 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 22·1 and 24·9 per 1000 in the two preceding weeks, further rose to 26·0 during the week ending Oct. 22nd. During the past four weeks the rate of mortality in the city has averaged 24·7 per 1000, the rate during the same period being 18·6 in London and 19·1 in Edinburgh. The 174 deaths registered in Dublin during the week under notice showed an increase of 7 upon the number in the preceding week, and included 20 which were referred to the principal zymotic diseases, against 19 and 18 in the two preceding weeks; of these, 8 resulted from diarrhœa, 7 from whooping-cough, 4 from "fever," 1 from scarlet fever, and not one either from small-pox, measles, or diphtheria. These 20 deaths were equal to an annual rate of 3·0 per 1000, the zymotic death-rate during the same period being 1·6 in London and 3·0 in Edinburgh. The deaths from diarrhœa, which had declined from 27 to 11 in the three preceding weeks, further fell to 8 last week. The 7 fatal cases of whooping-cough exceeded the number recorded in any week since May, 1897. The deaths referred to "fever," which had been 2 and 3 in the two preceding weeks, further rose to 4 last week. The 174 deaths in Dublin last week included 42 of infants under one year of age, and 34 of persons aged upwards of sixty years; the deaths both of infants and of elderly persons showed a decline from those recorded in the preceding week. Four inquest cases and 5 deaths from violence were registered; and 54, or nearly a third, of the deaths occurred in public institutions. The causes of 12, or nearly 5 per cent., of the deaths in the city last week were not certified.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments are notified:—Surgeons: R. H. J. Browne to the *Edgar* and afterwards to the *Alacrity*; C. R. Sheward to the *Edgar* and afterwards to the *Redpole*; F. Nimmo to the *Edgar* and afterwards to the *Pigmy*; W. Jackson to the *Plover*; and M. L. B Rodd, F. J. A. Dalton, and F. D. Lumley to the *Edgar*.

ROYAL ARMY MEDICAL CORPS.

Major Thompson proceeds to Woolwich for duty. Lieutenant-Colonel Kirkpatrick and Captain Jones are transferred to the Aden District, and Captain Sladdon from Bombay to the Nagpore District. Major Lane is posted to the Bombay District.

INDIA AND THE INDIAN MEDICAL SERVICES.

Lieutenant-Colonel McConaghey, Civil Surgeon, Lucknow, is appointed to the Visiting Medical Charge of Rae Bareli, in addition to his other duties, during the absence on deputation to the Jail Department of Dr. Simpson.

ARMY MEDICAL RESERVE OF OFFICERS.

Surgeon-Captain Augustus Kinsey-Morgan, 1st Dorsetshire Volunteer Artillery, to be Surgeon-Major.

The following notification is substituted for that which appeared in the *London Gazette* of Oct. 11th, 1898:—Surgeon-Lieutenant E. W. St. V. Ryan to be Surgeon-Captain.

VOLUNTEER MEDICAL STAFF CORPS.

The London Companies: Surgeon-Captain C. T. D. Urquhart, from the Aberdeen Company, to be Surgeon-Captain.

MEDICAL ARRANGEMENTS AT ARMY MANŒUVRES.

In *Truth* of Oct. 20th it is stated that the medical and hospital arrangements during the recent army manœuvres were inadequate. According to the regulations for mobilisation there should have been present 71 officers and 816 non-commissioned officers and men of the Royal Army Medical Corps, whereas the actual numbers available were 30 and 282 respectively, while apparently the horses required for the ambulances belonged to the Army Service Corps and had to do double duty. Mr. Labouchere is of opinion that it is not necessary to make the same preparations for dealing with the sick and wounded at manœuvres as it would be in a campaign, and yet he immediately afterwards enunciates the thoroughly sound dictum that "if these manœuvres are to serve the purpose for which they are intended it is as necessary that the conditions of actual warfare should be applied to the medical and ambulance arrangements as to any other department." In a succeeding paragraph the subject of "typhoid fever, euphemistically described as enteric," is dealt with, some rather curious statements being advanced. With the advice regarding the after-treatment of convalescent typhoid fever patients, however, it is impossible to disagree. Beyond question "extreme care" is needed "for a long time after the [apparent] disappearance of the disease, both in regard to the diet of the patient and keeping him from violent exertion," and doubtless the note of warning sounded by *Truth* will reach the ears of many a convalescent soldier whose friends are not "likely to possess any medical knowledge."

THE LATE SIR W. A. MACKINNON, K.C.B.

A handsome tablet has been erected to the memory of the late Director-General of the Army Medical Department, Sir W. A Mackinnon, in the chapel of the Royal Victoria Hospital, Netley, with which place he was for some time connected as Assistant Professor of Military Surgery. The tablet, which was erected by numerous friends of the late Director-General, bears the following inscription: "Sacred to the Memory of Surgeon-Major-General Sir William Alexander Mackinnon, K.C.B., Q.H.S., A.M.S., born at Strath, Isle of Skye, June 27, 1830, died in London October 28, 1897. He served in the Crimea with the 42nd Royal Highlanders, and through the Indian Mutiny on the personal staff of Lord Clyde; he also took part in the New Zealand and Ashanti (1873–74) campaigns, and closed as Director-General of the Army Medical Staff an honourable and active career, which extended over forty-three years. This tablet is erected by his brother officers and several old comrades and friends."

THE WAR OFFICE.

While Mr. Brodrick is to be congratulated on his promotion to the Foreign Office as Under-Secretary of State for Foreign Affairs we may add that the War Office will regret the loss of his services, for he has proved an able, energetic, and business-like official, and has not spared himself in mastering the details of army administration. In conjunction with Lord Lansdowne he has helped to carry out some important changes in the organisation of the army and, among other things, in the reorganisation of its medical service as well as in matters affecting army sanitation generally. Sir George Whyte, V.C., has taken up the post of Quartermaster-General, having, we are glad to say, quite recovered from the effects of the injury he sustained whilst serving as Commander-in-Chief of Her Majesty's Forces in India.

THE HEALTH STATISTICS OF THE ITALIAN ARMY.

The *Army and Navy Gazette* of Oct. 22nd, deriving its information from published official returns, states that the health statistics of the Italian Army for 1896 show that 151,438 were treated in hospitals and infirmaries out of a total strength of 204,382 men. There were 1184 deaths in all, of which infective diseases caused 536 (225 typhoid fever). The mortality was greatest in the first year of service and between the ages of twenty-one and twenty-three years.

THE SICK AND WOUNDED FROM THE SOUDAN AT NETLEY.

Her Majesty the Queen will, we understand, visit Netley Hospital on her return from Scotland to see the sick and wounded from the Khartoum expedition.

DIFFICULTIES UNDER THE INFECTIOUS DISEASES (NOTIFICATION) ACT.

To the Editors of THE LANCET.

SIRS,—A week or so after my first attendance on a case of scarlet fever the mother told me that she had noticed a rash on a child who had been sleeping with my patient and that the rash had been followed by peeling, which was now nearly at an end. I examined the cuticle carefully and had no doubt that this had been a mild case of scarlet fever now at the end of the desquamative stage. I thought it my duty to notify it, but struck out the word "urgent" which is printed on the envelopes addressed to the medical officer of health and inserted the words "desquamative stage," thinking that this would indicate—as there was already a case under treatment—that there would be no need for fresh sanitary measures. To my surprise I received a note from the medical officer of health next day in which the following passages occur: "The inspector visited the house at once to make usual inquiries." "The father was astounded to hear that the child had scarlet fever." "The inspector thereupon examined the hands and feet without finding any trace of peeling." "In the circumstances I have thought it desirable to mention the above facts and to ask you whether there may not perchance be an error of diagnosis." In a subsequent letter he says: "I think you should withdraw the notification. I do not see how I could possibly advise the committee to pass the certificate for the payment of the fee." I have since had a letter from the vestry referring to my "neglect to notify the case forthwith" (I may have allowed twenty-four hours to elapse between seeing the case and forwarding the notification), further stating that they "will decline in the present instance to pay the usual fee for your certificate." I should like to know if it is usual for sanitary inspectors to examine cases and correct the diagnosis of medical men. Also, if the vestry are within their rights in refusing to pay for a notification.

I am, Sirs, yours faithfully,

Kensington, Oct. 26th, 1898. ALFRED E. BARRETT.

*** We recommend our correspondent to read our pamphlet entitled "Difficulties under the Infectious Diseases (Notification) Act."—ED. L.

"VITALITY."

To the Editors of THE LANCET.

SIRS,—From Dr. Beale's letters it would seem he does not believe in the correlation, equivalence and transmutation of forces, and that one force may be a mode of another, as heat (and perhaps life) is a mode of motion. He seems to exclude the vital from all other forces and to regard it as *sui generis*, neither transmuted nor transmutable. Vitality, he says, "cannot be derived from non-living matter *or* from force," but may it not be derived from such matter *plus* force, as locomotive power is from coals and water *plus* heat? Professor Lindley, in his "Introduction to Botany," Ed. 1839, p. 358, says he had some raspberry plants before him as he wrote which had been raised from seeds taken from the skeleton of a man 30 ft. below the surface of the earth, who had been buried with some coins of the Emperor Hadrian. The seeds therefore were 1600 or 1700 years old. All this time they had lain without motion or change of any kind and so might have remained for ever if they had not been exposed to heat, light, air, and water. Before such exposure they might be regarded as so much *quasi* dead matter, waiting for forces to produce in it chemical activity, change, movement, germination—in a word *life*, which the matter *per se* and the forces *per se* could never have generated. As Dr. Beale denies that life can be derived from non-living matter and forces and as there was a time when our earth consisted of these only, how does he explain the first appearance of life upon it? A and B being the only things in existence, if C appears surely it must be derived from A or B or A + B?

I am, Sirs, yours faithfully,

D. HOOPER, B.A. Cantab., M.B. Lond.

Trinity-square, S.E., Oct. 24th, 1898.

To the Editors of THE LANCET.

SIRS,—My thanks are due to those members of the profession who have taken part in the consideration of that which I have long regarded not only as the most important of all the questions connected with every department of medicine and surgery but a question which has to do with the first principles of natural science and philosophy.

Seeing that the bioplasts, the several particles of living matter upon which the formation, action, and preservation of all the active tissues and organs of a living being depend, are less than the one-thousandth of an inch in length and diameter, and in many cases considerably less than this, the question of the nature of vital change—of vitality—must be considered from the microscopical point of view. I doubt whether anyone who studies the facts and observations to which I have referred will very widely differ from me as regards the conclusions he arrives it.

It is to be regretted that so far no one has criticised the views I have advanced from the microscopical side, which are based upon observations possible only during the last thirty or forty years. Even recently some naturalists, physiologists, psychologists, and pathologists, as well as chemists and physicists, have not only under-estimated the constantly increasing value of microscopical investigation in our endeavour to determine the nature of vital phenomena, but have calmly ignored the important bearing of facts ascertained by microscopical inquiry upon the problem of life. Consequently free discussion, in the absence of which the advancement of every department of natural knowledge must be retarded, has scarcely been commenced.

During the last few months, however, some encouragement has been afforded to students in microscopic investigation in England by the honours conferred upon Kölliker and Virchow, whose lives have been devoted to microscopical anatomy and pathology, while Lister stands pre-eminent in the recognition by the State of his labours in an all-important department of minute investigation.

Dr. T. Glover Lyon's suggestions take us far beyond the visible minute bioplasts consisting of living matter to be found in all those parts of a living organism where vital action proceeds. Is not the state of the "tissue" of a living animal as contrasted with the "tissue" of a dead one dependent upon the never-ceasing interstitial currents of fluid through every part of it—a circulation which is set up and maintained as long as the bioplasm lives, but ceases the instant it dies? "Ethereal forces" and "ethereal waves" also go far beyond anything I can hope to study. Tissue and bioplasm I have seen and have demonstrated to others.

Dr. Harry Campbell will force upon me notions with which I am not concerned. When he has defined what he means by "evolution" it will be soon enough to discuss with him the question of the "evolution of vitality." Surely he may "take his individual *homo* and trace in imagination his evolution from, let us say, his piscian ancestry" to his heart's content, and "travel down his long ancestral lines," and even become "more and more involved," without trying to involve me and my efforts to learn a little more about living matter and the formation and action of tissue in interminable, impossible travel. From the thoughtful interest he has shown, however, I do not despair of his becoming a convert to vitality, and I feel sure if he will only consider the changes which take place, say, in the limbs of a child, as by the process of growth the distance between the peripheral extremities and the brain gradually increases, he will no longer regard growth as it occurs in all things living as a change in any way akin to a physical process such as aggregation—man as a machine constructed or built by the Sun, or man's life to be physical and chemical, and I hope he will regard all vital evolution as absolutely different from all physical evolution, as is life of every kind and of every period from any physical change at present known. But whatever may be our differences all workers and thinkers will acknowledge with Dr. Harry Campbell the absolute truth and eternal application to all our achievements of

Digitized by Google

Hamlet's profound philosophy with which his letter concludes.

Mr. O'Regan seems to think, with some other authorities, that life is a property of matter and argues that "as matter never had a beginning life as a property of matter never had a beginning"; but does not very much matter exist without the property in question? Still though I may not add anything "to our knowledge," I trust I may escape the terrible fate of being taken "round and round the circle for ever," and I hope Mr. O'Regan will treat my vitality with a little more kindness and consideration than he extends to the assumption that matter has "a real existence."

I am, Sirs, yours faithfully,

Oct. 25th, 1898. LIONEL S. BEALE.

"WHAT IS 'FIRST AID'?"

To the Editors of THE LANCET.

SIRS,—I quite agree with Mr. Valentine Matthews that it is time that a more definite course was laid down for lecturers and examiners in "first aid." The late Surgeon-Major Shepherd's Handbook has been improved of late, but it is still very unsuitable for a text-book. What good purpose can possibly be served by teaching a class the number of bones in the spine, chest, wrist, and hand, or the total number in the body? The description of the cavities of the heart and its valves is another among the many unnecessary complications. Yet the lecturer dare not omit these details lest a short-sighted examiner fail to pass his class. I once had two large classes of working men "ploughed" almost to a man on the subject of poisons. I confess my teaching had gone little beyond the proper use of an emetic, but for the type of student I am certain it was quite enough.

What is wanted is a book prepared with the greatest care, not one put together in a hurry, as was, confessedly, the present one. In it all that is essential should be printed in large type, with perhaps a few further facts for more ambitious students in a smaller type. The matter should be arranged in logical order. A more complete book could be easily arranged in less than half the space. Examiners should be instructed to examine only on the text-book, or at all events to ground their report on a knowledge of it. A page might be devoted to a list of facts which *must* be learnt and then both lecturer and examiner would be on firm ground.

There are many other details which might be improved in the present course. Thirty is far too many for one man to instruct practically. Paper work should be abolished for all. Such knowledge is often practically useless, and the present distinction between literates and illiterates is illogical. The practical part of a lecture should be the longer. The present direction that half an hour of each lecture should be devoted to practical work is absurd, for with a class of thirty it would mean five minutes' practical work to each student during the course. I try to arrange that each pupil does all the operations at least twice, but of course that means cutting down the "unpractical" part of each lecture to little over half an hour.

I have not much faith in representative committees, and question whether Mr. Matthews's scheme for such would produce a more satisfactory course. I would rather see one able man appointed who should write a new text-book and submit it to all the lecturers and examiners. Those who felt themselves qualified to criticise might apply for, and pay for, a copy, and thus expense to that excellent association the ambulance department of the Order of St. John of Jerusalem might be avoided.

I am, Sirs, yours faithfully,

Ottery St. Mary, Oct. 24th, 1898. CLAYTON JONES.

"THE WATER TEST AS APPLIED TO SEWER CONNEXIONS."

To the Editors of THE LANCET.

SIRS,—I think this is a matter which should be publicly noticed as in the course of my experience I have found that the so-called water test as applied by some local authorities to sewer connexions is a farce and I have no doubt many engineers, architects, and builders have had the same experience. As an instance a few weeks ago a client of mine bought a house in one of the suburbs which he decided to have redrained. A deposit of £5 was paid to the local authorities for putting in a new 4-in. connexion from the sewer to the fence. The house-drains were put in under my supervision, laid on concrete beds, and the joints were properly made with cement and allowed to set for four days before the first water test was applied. The joints successfully resisted a pressure of 5 lb. to the square inch. The pipes were then surrounded with concrete and when it had properly set the trenches were filled and watered in and no ramming was allowed until 2½ ft. of soil covered the pipes. The whole of this work was examined by the local sanitary inspector, who was as particular as I was myself about the soundness of joints, &c. The connexion from the sewer to the fence was put in in a very different manner. The joints were made with cement and tested by the local authorities as soon as they were made, before even the cement was dry, and I noticed a workman ramming the clay into the trench a few inches only above the pipes which had no concrete either below or around them. The drain was filled with water which was run off immediately and this was the water test. Further comment is needless. This is a fair sample of what is constantly going on.

Without going into the legal question as to whether local authorities have any right to make a charge for sewer connexions at all, which I very much doubt, I contend that as my client paid £5 for this connexion he should be allowed the privilege of having it examined by his representative, to see that he got value for his money, which in my opinion he certainly did not. If the house-drains had been laid and tested (?) in this way, they would have been promptly condemned by the local authorities. Why, then, should not the local authorities be compelled to do their portion of the work as thoroughly as they make the house-owner do his? for at present they carry out this work in a most unsatisfactory way. If the water test is to be applied to those connexions at all, why should it not be applied properly, as in the case of the house drains? There is no doubt that the ramming process has shaken off the wet cement from the joints of the pipes. To fill a drain with water when the joints have just been made and to let the water run off immediately is *not* applying the water test. A paper bag will hold water until the paper becomes saturated, and so will a drain until the joints become saturated; but then, if the water is allowed to remain in and the cement joints are not set the pressure of water in the drain will force the cement out of the joints. It should be remembered that a great many sewer connexions are a very few feet below the road surface, and if a stoppage occurs the sewage escapes through the leaking joints and saturates the surrounding ground with results known to every sanitarian.

I think this is a subject that should prove interesting to medical officers of health as there must be many miles of this defective drainage both in London and the suburbs. If it is argued that the trenches in the public roadway cannot remain open long enough to give the pipe-joints sufficient time to set, then why should not heavy iron pipes with caulked lead joints be used for those connexions?

I am, Sirs, yours faithfully,

Wimbledon, Oct. 21st, 1898. JOHN W. MAYNE.

"PRACTICAL HINTS ON CYCLING FOR COUNTRY PRACTITIONERS."

To the Editors of THE LANCET.

SIRS,—Your cycling readers will thank Dr. Emmerson for his paper on "Practical Hints on Cycling for Country Practitioners," in THE LANCET of Oct. 22nd. The hints are valuable, not only for medical practitioners, but for all cyclists, whether ladies or gentlemen. The bicycle has made a revolution in travel and is giving health and strength to those who use it in moderation. I see that the machine is much in requisition among the young people of the theatrical profession, who wisely take advantage of it to get as much country air as possible during their provincial tours. It is wonderful the long distances ordinary riders can cover without much fatigue. A young girl of my acquaintance, ten years of age, rode to a watering-place upwards of forty miles from her home and afterwards spent the greater part of the day on the sands playing with her little friends.

But a greater feat than this was performed recently by the Rev. Henry Watney, rector of Canwick, Lincoln, who rode from Lincoln to a place six miles beyond Newbury in Hants, a distance of 165 miles, in one day, and on the following day he did not feel the least fatigued. Mr. Watney strongly

Digitized by Google

advises that food should be taken every 50 miles, if it were only milk or bread-and-milk. Many people would feel rather tired at the end of a railway journey of 165 miles. I am afraid bicycling is putting constitutional walking out of fashion—in fact, numbers of good bicyclists are bad walkers and tire very quickly.

I am, Sirs, yours faithfully,
WILLIAM O'NEILL, M.D. Aberd., M.R.C.P. Lond.
Lincoln, Oct. 24th, 1898.

MEDICAL FEES FOR LIFE INSURANCE EXAMINATIONS.

To the Editors of THE LANCET.

SIRS,—You are no doubt aware that it is the general practice of life insurance offices to pay a fee of one guinea for the medical examination of proposers for insurance, but that when the sum assured is small only half that fee is allowed, the reason being that the smallness of the premium will not admit of the payment of the full fee. It may interest you to learn that, as the result of the discussions in the section for life insurance at the recent meeting here of the British Medical Association, the directors of this office have decided to double the fee when the sum assured is £2000 and upwards, thus allowing two guineas for the medical examination in these cases.

I am, Sirs, your faithfully,
DAVID PAULIN,
Manager, the Scottish Life Assurance Company,
Edinburgh, Oct. 26th, 1898. Limited.

A CORRECTION.

To the Editors of THE LANCET.

SIRS,—The statement on page 1090 of the issue of THE LANCET for Oct. 22nd that I am a candidate for the appointment of extra-physician to the Sick Children's Hospital is incorrect.—I am, Sirs, yours faithfully,
Edinburgh, Oct. 26th, 1898. J. S. FOWLER.

POOR-LAW MEDICAL APPOINTMENTS.

To the Editors of THE LANCET.

SIRS,—I shall feel very much obliged if through the medium of THE LANCET you would answer the following questions: 1. Is it compulsory that all Poor-law medical appointments should be advertised by a board of guardians? 2. Is it legal to appoint a medical officer to a Poor-law district who resides out of the district when other eligible men reside in the district and are applicants for the same?

I am, Sirs, yours faithfully,
Oct. 19th, 1898. MEDICUS.

*** The guardians are not bound to advertise their vacancies in point of law, but when they proceed to appoint without having previously advertised the vacancy they render themselves very liable to public criticism, and if the question was raised by the Local Government Board they would have to justify their action and show that the person whom they appointed was very highly qualified for the post in every respect. As regards the second question, a district medical officer is not necessarily obliged to reside within his district though it is very desirable he should do so. In point of law the guardians are not obliged to appoint a gentleman residing within his district to the medical officership of that district, but, other things being equal, it is eminently desirable that he should do so; and if candidates residing within the district and otherwise qualified came forward the guardians would again have to satisfy the Local Government Board as to the grounds for their action to the contrary. If our correspondent thinks it worth while he might very well submit these points to the Local Government Board, with whom the confirming of such appointments rests absolutely. As a rule, however, these appointments are so poorly paid and service under the guardians is so irksome that medical men rarely find it worth while to go out of their way to secure such appointments.—ED. L.

SANITATION AND DIPHTHERIA AT TUNBRIDGE WELLS.

(FROM OUR SPECIAL COMMISSIONER.)

FOR some time there has been an exceptional prevalence of diphtheria at Tunbridge Wells. The Local Government Board complained that this matter had not received sufficient attention and finally held a local inquiry on the subject. The report giving the results of this inquiry has not yet been published. The deaths from diphtheria during the last ten years, from 1888 to 1897, were for each successive year as follows: 9, 3, 5, 4, 5, 9, 5, 9, 14, 10. In 1896 there were 67 cases of diphtheria notified, resulting in the 14 deaths mentioned above, and in 1897 no less than 117 cases of diphtheria were notified, though there were only 10 fatal cases. The fact that so many cases produced so few deaths may be in part due to the extensive use of antitoxin. The medical officer of health is always ready to supply antitoxin gratuitously for use among the poor. Considering that the population of Tunbridge Wells barely exceeds 30,000 the above figures show, not merely a high proportion, but a steady increase in the number of cases of diphtheria, which has continued during the present year, and these were the facts which led the Local Government Board to institute a special inquiry. In other respects, however, the death-rate of Tunbridge Wells is not high. The zymotic death-rate only amounted to 0·97 per 1000 in 1896, while that of the country generally was equal to 2·18 per 1000, and in 1897 it was equal to 0·95 per 1000, as opposed to 2·55 per 1000 for London and 2·15 per 1000 for England and Wales during the same period. The mean general death-rate for the ten years from 1888 to 1897 amounts to 13·7 per 1000, and amounted to 12·22 per 1000 in 1897. But if from this we deduct the deaths occurring among visitors who had resided in the borough for a period of less than three months the death-rate for last year is reduced to 11·1 per 1000. At the same time it must be borne in mind that the birth-rate is exceptionally low—namely, 20·32 per 1000 in 1897, as against 29·7 per 1000 for England and Wales. Not only are there few births, but the infant mortality is low. In 1896 the deaths of infants under one year of age was equal to 117·6 per 1000 born, while for England and Wales the proportion was 148 per 1000 born. In 1897 the figures for Tunbridge Wells amounted to only 87·8 per 1000 born, as against 156 per 1000 born in England and Wales. If judged only by these statistics it would seem that Tunbridge Wells is an exceptionally healthy place. The question, however, arises whether this low death-rate is the result of good sanitation and administration of the town or the consequence of the special character and circumstances of the inhabitants.

The medical officer of health in his annual reports has several times pointed out that at Tunbridge Wells there is an exceptionally low birth-rate, an extra complement of aged lives, an excess of invalid visitors, a very small proportion of operative workers, and a great excess of opulent people. As a matter of fact, Tunbridge Wells can hardly be considered as a town in the usual acceptation of the word. There are very few streets where the houses touch each other. It is rather a vast accumulation of villas and mansions standing in their own grounds and separated from each other by trees, gardens, and flowers. A great number of the inhabitants are thus leading country rather than town lives and they are able to supplement the abundant supply of pure air with all the ease and comforts which the possession of ample means enables them to secure. Under these circumstances the death-rate ought to be exceptionally low, and the question arises whether with a more efficient sanitary administration the death-rate might not be lower than that on record. In any case, many of the inhabitants who ought to know are far from satisfied with the present state of affairs. Nor is this dissatisfaction a mere platonic expression of opinion. It has given rise, on the contrary, to an active agitation and has brought forward fresh candidates for municipal honours, who base their principal claim for support on their determination to press forward energetic measures of sanitary reform. Strange as it may seem, considering the luxurious appearance of most of the dwellings and the large gardens with which they are surrounded, the chief complaint is that of overcrowding. The

Digitized by Google

grievance arises partly from the fact that there is no competition in the sale or leasing of land for building purposes. It nearly all belongs to three or four large land-owners who do not want to be bothered with poor tenants. They are willing enough to see villas and mansions arise on their land, but they have a strong objection to workmen's cottages. Such dwellings, they think, would depreciate the value of the surroundings, and therefore they refuse to let their land on building leases unless high-class houses are to be erected. Thus, though the working-class population is not numerous, there is a much keener demand for workmen's cottages than for middle-class villas. But anyone seeking to supply this demand would find it almost impossible to obtain the necessary land. Yet, on the other hand, if a big villa or residence is erected the tenants bring with them a coachman and they require the services of gardeners and others who do not live in the villa. Where, however, are these attendants to live? They must rent one of the few workmen's cottages that do exist, and as this necessity is most imperative they are compelled to bid against each other. Thus the rents for workmen's cottages have risen in a fabulous manner; and now it often happens that a third of a workman's earnings is absorbed merely in the payment of rent. Under these circumstances the tenants of workmen's cottages are obliged to take in lodgers so as to help them to pay the rent, and this occasions the overcrowding.

That this grievance is serious is proved by the petition which was drawn up on the subject some time ago. It was entitled "An Urgent Necessity" and was worded as follows:—

> We, the undersigned, consider that for some years the number of houses for the working classes resident in Tunbridge Wells has been and still is grievously deficient. We know from our own experience that much overcrowding has resulted, and are convinced that evils, both physical and moral, have been prevalent in consequence. We urge that efforts should at once be made to discover the best means of removing this serious danger to the physical welfare of our town and its general reputation as a health resort.

This petition was signed by thirty out of the thirty-two local medical practitioners. The two medical men who did not sign were in no way opposed to the petition, but could not testify that they had personal knowledge of the overcrowding. On the other hand, all the Poor-law guardians, all the clergy, all the ministers of Dissenting chapels, all the trade union officials and the chief house-agents without exception signed the petition. Finally, the petition was confirmed and adopted at a public meeting convoked by the mayor of the borough and held on Feb. 25th, 1897. A somewhat elaborate house-to-house inquiry was instituted in the poorer quarters. It was then shown that cottages containing only four rooms and a small lumber room were rented at 7*s.* and sometimes even 8*s.* per week. There certainly is one little lane where some weather-board cottages are rented at 4*s.* a week, but these were such wretched structures that they had to be rebuilt. To avoid, however, the submitting of plans to the town council each wall was pulled down separately and the work done was described as repairs and not as rebuilding. Where for 7*s.* 6*d.* or more a cottage with six rooms can be obtained, it will be found that, though built for one single family, it is inhabited by two or three families. Of course, there is not the necessary accommodation. The family that occupies the kitchen may be able to cook a decent meal, the other families cannot do so.

As the demand for these cottages is so keen the landlords can afford to neglect necessary repairs. If the tenants are not satisfied they can easily be replaced by others who will not be so difficult to please; therefore it is not surprising to hear that many of the cottages are in a very insanitary condition. Thus in some cases it has been found that the house drain, instead of communicating direct with the sewer, first passed under a whole row of cottages. Then these drains were so badly built that they burst and saturated the subsoil. On pressing on the thin boarding of the cottage floor the gurgling of the sewage underneath could be heard. When a case of diphtheria occurred in such a cottage the flooring was taken up and the drain was relaid. But sometimes there were other cases of diphtheria after these repairs had been effected and some people concluded from this that sanitation was of no use as a preventative for this form of disease. They forgot, however, that though the drain had been repaired the subsoil remained in a polluted condition.

It seems quite evident that sanitary matters have, at least in the past, been much neglected. The building of houses over old brick drains has been allowed and it would still be difficult to say how some parts of the town are drained. The medical officer of health, Mr. William Stamford, and the sanitary inspector, Mr. James Cave, have not failed to point out some of these defects in their official annual reports. Thus, dealing with the 14 deaths from diphtheria which occurred in 1896, Mr. Stamford says that this disease "was prevalent in the boundaries of the borough, at Rusthall and Newton, and children attending an infant school which was in a bad state of sanitation became infected. The school was at once closed, as soon as it was found to have been a source of infection." Concerning house sanitation the medical officer of health advises the town council to avail themselves of the Act of Parliament bearing upon this matter and to erect about 200 cottages for "the exclusive occupation of the respectable and provident poor." This recommendation is all well and good in its way, but there are two objections—first, that the town council did not seem at all inclined to thus run in competition against private interests; and secondly, that from the sanitary point of view it is precisely those poor who are neither provident nor respectable that require the most attention and legislative interference. Both the sanitary inspector and the medical officer of health protest against the keeping of poultry, rabbits, and sometimes even pigs, in small back yards; but it is because the people are poor that they seek to eke out their slender earnings by rearing such animals. Now one of the most evident causes of this poverty is the exorbitant rents charged. If the municipality would provide cottages at a low rent then they would have the right to stipulate that poultry, &c., should not be kept on the premises.

Concerning the 117 notified cases of diphtheria which took place in 1897 the medical officer of health states that an outbreak occurred at Rusthall and Lower Green on the boundary "which was traceable to the water-supply, derived from a spring at Lower Green, not forming part of the town supply. This spring was found to be contaminated, the dip-hole receiving a back flow from a contaminated pond. The water was examined by Dr. Stevenson and on receipt of his report water was supplied gratuitously from a standpipe and steps were taken to enforce a supply to each house from the borough mains. Notice was also posted that the water from the spring was unfit for domestic use." On the other hand, this town supply does not seem to be all that can be desired. Land has recently been purchased to establish filter-beds, and it is to be hoped that these will be placed in working order at the earliest possible date. So also has Part III. of the Housing of the Working Classes Act (1890) been recently adopted by the town council and some steps have been taken for the acquisition of land. The question is, however, whether the new town council, to be elected at the commencement of November this year, will show more energy and a genuine desire to carry out an effective scheme for the housing of the working classes. It will likewise be necessary to act with much more rigour against the owners of bad property. In his report for the year 1897 the sanitary inspector says: "Many drains which have been found defective have been repaired and reconstructed and many hundreds of defects in sanitary fittings have been attended to. Many houses, however, still remain in a condition which renders improvement necessary." Evidently what is wanted is a house-to-house inspection and the careful testing of every drain. But even when this is done it is very possible that a new drainage scheme will have to be devised, at least for some portions of the town. In his report for the year 1896 the medical officer of health says that "during the year a large number of surface sewer ventilators have been removed or closed and nearly all the open gullies have been trapped, ventilation for the sewers being provided by a ventilation shaft whenever required." But in the following year we find that still more complaints were made as to the effluvia coming from street sewer ventilators and gullies. Evidently the ventilation shafts were not placed wherever required or were not effective, for now the medical officer of health recommends that the whole subject of sewer ventilation should be submitted to, and studied by, sanitary engineers. The real fact is that in all probability the sewers in many instances are not properly laid and are not self-cleansing, and hence the constant complaints as to the escape of unpleasant effluvia. Till these defects are remedied the bad odours had better escape on a level with the streets than inside the houses or be conveyed by shafts to the neighbourhood of the bedroom

Digitized by Google

windows. A bad smell has often been described as a sanitary sentinel, and if the sewers are not properly built the inhabitants of Tunbridge Wells had better be made aware of the fact by the constant escape of bad odours in the streets.

Whether all these sanitary defects are the only cause of the increase of diphtheria it is difficult to say. Doubtless they have aggravated the evil. But there can be no denying that school attendance, though not the original cause of diphtheria, contributes largely towards its spread. Children lick their slates, put their pencils in their mouths, bite from the same apple, and instead of taking a glass put the water-tap in their mouths. Thus by means of their saliva and directly from mouth to mouth the disease can be communicated from one child to the other. It is difficult to see how this can be altogether prevented. Even adults, when duly warned, are often most careless and we cannot expect greater forethought from little children. Nevertheless, more severe regulations could be established than are at present enforced and the school teachers should watch, and reprove, or advise, the children more frequently in regard to such matters. Again, it must be confessed that the climate of Tunbridge Wells is perhaps not so favourable as is generally supposed. It has been urged that diphtheria is more prevalent in the presence of damp and there is a considerable amount of clay soil. The rocks which stand out on the common seem to indicate that the town is built on sandstone. But this is not the case. In some places there is clay to a depth of 14 ft. From the Pantiles down to the new athletic grounds the soil is practically all clay, and where there is sandstone there are indentations which retain water and this in evaporating occasions fog and dampness. As a proof of this it may be noticed that the trees outside the town are covered with lichen. The soil, in fact, alternates between sand and clay. The water does not escape easily in the subsoil; therefore it ultimately evaporates and hence there is probably more damp than is generally supposed. In the absence of careful hygrometric observation it would, of course, not be safe to dogmatise on this point, but it seems likely that there is more damp than is desirable.

On the other hand, visitors to Tunbridge Wells will be glad to hear that a system for the giving of sanitary certificates to lodging- and boarding-house keepers has now been instituted. Some time ago Mr. George Abbott, a retired medical practitioner residing in Tunbridge Wells, started an agitation in favour of such certificates. At first the town council were not inclined to take the matter in hand, and then Mr. Abbott said he would endeavour to form a private association to inspect houses and certify to the condition of their drains, &c. Finally, however, the town council yielded and themselves organised a service of this description. The sanitary certificates issued during the first year have brought in to the borough an income of £30 paid as fees for inspection and certificates. This measure will add greatly to the attractions of the town and will help to dispel whatever alarm may be caused by the cases of diphtheria which have been recorded and by the insanitary condition of certain quarters and houses.

WE have received the following communication from a resident, which is in many ways so confirmatory of our Special Commissioner's report that we think it interesting to print them next each other.

To the Editors of THE LANCET.

SIRS,—Tunbridge Wells has been visited within the past eighteen months with some pronounced outbreaks of diphtheria, confined mainly to the eastern and northern divisions of the borough, though several cases have occurred from time to time in the south and south-west, as well as at Rusthall, a neighbouring village about 1½ mile distant in a westerly direction. As is well known, the town is famed for its excellent and somewhat chalybeate water, its bracing air, and its beauty of inland scenery, while the district abounds in beds of secondary iron ore. The main water-supply of the town is derived from reservoirs, 7¾ acres in extent, situated at the village of Pembury, about 3½ miles distant, supplemented by water from bore-holes. There is a constant supply; it is, however, generally admitted that it is desirable that filtration should be carried out owing to the presence of a variable amount of harmless vegetable débris. The soil of Tunbridge Wells may, speaking broadly, be divided into two main divisions—that in which the sandstone rock predominates and that in which there is an admixture of sandstone and clay, by far the most interesting geological feature being the peculiar character of the rocks which underlie the district. The population is about 30,000, the birth-rate is 20·32 per 1000, while the corrected death-rate is 11·1 per 1000—a rate which will compare very favourably with other health resorts. The corporation have adopted several of the most salutary Acts of Parliament relating to public health questions—in particular the notification of infectious diseases; the general sanitary regulations relating to dairies, cowsheds, and trades; the housing of the working classes and public baths; and they have secured a generally efficient system of street main drainage, street lighting, watering, and sweeping. During 1897 three infectious diseases were particularly prevalent within the limits of the borough—namely, scarlet fever, 129 notified cases; diphtheria, 117 notified cases; and whooping-cough, which caused 12 deaths. The cases of scarlet fever were, on the whole, of a mild type. The cases of diphtheria centred in the main among the poorer labouring classes living overcrowded in more or less insanitary houses, affecting mostly the children attending three of the Church schools. A localised outbreak also occurred at Rusthall and Lower Green, within two miles of the borough but in part outside its boundary. This outbreak was clearly traced to the water-supply, which was derived from a spring at Lower Green and did not form a part of the borough general main supply. There was undoubted evidence of contamination of this spring, the dip-hole receiving a back flow from a contaminated pond. The prevalence of diphtheria in the borough is, by a general consensus of expert opinion, due to the day schools and, moreover, it is noteworthy that the first cases during the earlier half of this year occurred almost entirely among those children attending one or other of two parish schools in particular. The local urban sanitary authority was not at the time able to stamp out the disease completely; consequently a series of cases has been kept going by means of personal infection among the children, among the most frequent and effectual means being the cup at the street drinking-fountains, the proved fact that children suffering from the disease in question or those convalescent, though possibly still infectious, had given sweetmeats which they themselves had partially dissolved in their own mouths to other children, the constant carelessness of their parents as to the common use of feeding utensils, cups, spoons, and of all articles used to wipe discharges from the mouth and nostrils, including vessels used to receive sputa, &c. The mortality among the 117 notified cases in 1897 was 10. It is comparatively a difficult and intricate matter to prosecute a very searching inquiry into the absolute *fons et origo* of these outbreaks in the town. The water- and milk-supply generally being to all appearances above suspicion, we are naturally led to an examination of the system (or its absence) of the house-drainage among the dwellings of the poorer classes, the disease never having gained much ground among the well-to-do and usually better-housed residents. One general conclusion which may reasonably be drawn is that the drainage in many of the houses of the poor is undoubtedly defective and that in some instances there is also overcrowding, coupled with the keeping of fowls and other domestic animals in confined spaces such as unclean backyards and outhouses. The chief points to which sanitary efforts should be directed appear to be the reconstruction of a large number of house-drains, the proper fitting of both inside and outside water-closets with flushing tanks, the erection of ventilation shafts, the total abolition of all cesspools, the fitting of satisfactory manholes, soil-pipes, and approved traps, and the supply of water from the town mains to every house. As there have been frequent indications of mild cases of tonsillitis, pharyngeal catarrh, and "sore-throat" occurring in the neighbourhood of infected houses it would appear essentially important for local practitioners to "look out" for any such "doubtful cases," treating them upon prophylactic lines as if they were actual cases of diphtheria, as well as to aim at prompt and complete isolation of all first cases, the corporation having provided an isolation hospital. It would also be advisable if all cases of illness in which children have been sent home from school were visited at once, the teachers endeavouring to render every assistance to the medical officer of health of the borough as well as to the other local members of the profession.

I am, Sirs, yours faithfully,

RESIDENT.

THE BATTLE OF THE CLUBS.[1]

(FROM OUR SPECIAL COMMISSIONER.)

TUNBRIDGE WELLS.

Position of the Profession at Tunbridge Wells.—A Good Opportunity for constituting a Model Public Medical Service.—Abuse of the Friendly Societies.—Resignation of Consultants and Club Medical Officers.

MEDICAL MEN engaged in practice at Tunbridge Wells should enjoy an exceptionally fortunate position. There are comparatively few poor people in the town, but there are many invalids, and these nearly all belong to the wealthier classes. There are no large manufactories at Tunbridge Wells. The working classes of the town are for the most part connected with the building trades or work for retail shops, for some timber sawing-mills, or as gardeners, coachmen, stablemen, &c. Among the poorer sections of the community lodging-house-keepers probably form one of the most numerous classes. There is some poverty undoubtedly, but this cannot in any way be compared with the intense and widespread misery which prevails in the large manufacturing and commercial centres. Tunbridge Wells consists in the main of handsome villas and mansions and of the larger-sized type of house in which private furnished apartments are let to the numerous visitors who annually spend some weeks in this favoured locality. Under these circumstances it might have been thought that the medical practitioners of this town would not have suffered much from those economic conditions which compel medical men in other neighbourhoods to form unions for the sake of defending their material interests. As a matter of fact, however, this is not the case. The battle of the clubs has been fought at Tunbridge Wells as elsewhere, and there are also complaints of hospital abuse in that town. Certainly on investigating closely these grievances it became evident that they were not so acute or so widespread as in other and larger towns which I have visited; still, they do exist, and are sufficiently serious to justify complaints and to point to the need of organised action.

The two most important medical institutions in the town are the Provident Dispensary and the Friendly Societies' Medical Association. The former was started to relieve the pressure upon the hospital. Patients provided with a subscriber's letter of recommendation were able, according to the old rules, not only to go to the hospital, but they could request the house surgeon to visit them in their own homes. This outdoor work became too frequent and too irksome; also it was thought that the facility with which medical aid was obtained from the hospital would tend to pauperise a number of people. It was therefore decided to start a provident dispensary, to be supported by the subscriptions of the members and by voluntary donations. Thus it assumed at once the aspect of a charity and of a provident club. During the first year of its existence—namely, in 1877-78—the income consisted of donations £40, annual charitable subscriptions £83, and subscriptions to life governors' fund £137. Altogether £260 were charitably contributed. The payments made by members amounted to £410 and there were remaining on the books at the end of the year 1260 members. The contributions made by the members have greatly increased while the charitable donations and subscriptions have decreased. Thus in 1897 there were 2496 members who paid £619, while the charitable donations and subscriptions only amounted to a total of £118. The terms of payment for adults above the age of fourteen years is fixed at 1½*d.* per week and for children under fourteen years of age 1*d.* per week, but no more than three children in any one family need be paid for. Thus the maximum payment for one family is 6*d.* per week. Taking last year's figures, it would appear, however, that families with more than 3 children are the exception, for only 96 children are entered as entitled to gratuitous treatment, though the total number of members under fourteen years of age amounts to 822. The rule is that all the family must join unless any member already belongs to some other club which provides medical aid.

[1] A reprint of the previous articles on the above subject has been published in book form entitled, "The Battle of the Clubs," and can be obtained from THE LANCET Office, price 1*s.*

The question is whether the Provident Dispensary, being organised on this basis, has given rise to abuse. According to Rule 11, "any person whose average gains or wages do not exceed 35*s.* weekly may (subject to approval) be members on paying regularly and in advance their subscriptions." The wording of the rule, it will be seen, is extremely vague, for it does not state whether the wage limit applies to the joint earnings of the whole family or only to the individual member. In the latter case the limit would be far too high. Nor is there any systematic method of seeing that this rule, whatever way be its meaning, is strictly enforced. At the same time it is on record that several members have been expelled because they were too well off to belong to such a society. One of the medical officers of the dispensary assured me that he had during the course of the last year compelled several members to leave the dispensary and to call in private practitioners and pay the ordinary fee. On the other hand, when called upon to attend persons who are really poor, my informant explained that he refused to run up bills which he knew could never be paid and therefore would not attend poor patients unless they joined the dispensary. From other sources I learnt that a labouring man who had so far prospered that he was able to take a shop was urged to leave the dispensary and did so. There was another case of an assistant who, having taken a shop of his own, also left. It is true that in six months he was unsuccessful and is now working for wages once more, so perhaps he would be readmitted. In spite of these few incidents it seems that in actual practice the less said about the rules the smoother matters work and, on the other hand, the medical men of the town have no great complaint to make. It is generally recognised that there is some abuse, but it does not amount to much, and though no trouble is taken to find out such cases there is every disposition to put an end to any abuse which may be accidentally discovered. Nor can it be said that medical men attached to the dispensary are sweated or in any way exploited. On the contrary, after the payment of working expenses all the money received is divided between the six medical officers attached to the dispensary in proportion to the number of members they have on their books. Thus, last year, out of receipts amounting in all to £786 the medical officers received £447. With the balance the dispenser's salary of £91 10*s.*, the rent and taxes (£51) the drug bill (£73) and other smaller items were paid. Confinements are not included in the medical aid given by the dispensary, but it undertakes to collect weekly subscriptions of 1*s.* so as to pay the medical man attending a fee of one guinea.

The real grievance against the dispensary rests in the fact that the number of its medical officers is limited to six. This has helped to create a privileged class of practitioners and has driven others who could not join the dispensary to accept positions of a somewhat degrading description in the service of speculating insurance companies. In defence of the dispensary it may be said that it does not knowingly tolerate any abuse, that it seeks to check any touting proclivities on the part of its canvassers, and that it cannot employ more than six medical officers because there are only six working days in the week. The latter excuse is very weak. There might be more than one consulting-room, more than one medical men present at the same hour, or different medical men might attend at different hours. That some such arrangement would be practicable is proved by the fact that some time ago an effort was actually made to increase the staff. Two general practitioners having succeeded in establishing well-attended private clubs were sounded as to whether they would not join the Provident Dispensary and bring their members over with them. There is yet another grievance against the dispensary—namely, that the rule by which it is necessary to be a member for two months before receiving medical aid is not always observed. Some persons, it is said, only join when they are actually ill and pay two months' subscriptions on joining. Altogether, and to sum up, the dispensary is the least abused of the charitable institutions of the town. The reforms needed are a clearer definition and more strict application of the wage limit and the admission of all resident fully-qualified practitioners as medical officers of the dispensary if they desire to undertake that style of work. Such, in any case, were the only suggestions made to me during the course of my inquiries. For my part, however, I do not see why the medical practitioners of Tunbridge Wells should not aspire to place themselves on a level with the more progressive towns of the kingdom. The Provident Dispensary is managed by a committee of twenty

Digitized by Google

laymen and clergy. The only excuse, as far as I can see, for the existence of this committee of totally unqualified persons is that they represent the charitable donations made to the institution. These, however, amounted last year to only £118, and it seems to me it would be well worth while sacrificing this sum if by so doing the institution could be placed entirely in the hands of the profession. It would form a splendid basis for the establishment of a public medical service. After all, the best method for abolishing medical aid associations, clubs, &c., is for the profession to establish a model institution of its own open to all local practitioners and managed exclusively by the medical men themselves. Then no practitioner would have any excuse for selling his services to a speculating commercial concern; if he wanted club patients he could join the public medical service. All patients who could not pay the usual fees would have the option either of joining this institution as subscribers or of claiming relief under the Poor-law. The battle of the clubs would be terminated, for the medical clubs would cease to exist.

The next most important institution is the Tunbridge Wells Friendly Societies' Medical Association. This amalgamation of friendly societies was established in 1882. According to the published accounts this society has about 4000 members, a figure which includes 1000 juveniles. The income from subscriptions paid by these members last year amounted to £653, and the total income to £774. Out of this large sum the medical officer who is employed by this institution and is debarred from private practice received as his salary and for extras, which presumably include midwifery fees, the sum of £308 11*s.* 9*d.* A locum tenent was paid £3 3*s.* Evidently the medical officer did not enjoy a long holiday if his absence could be covered by a fee of only three guineas. Yet he must have been sadly in need of repose, for we find it on record that the number of visits paid to patients in their own houses during the course of the year amounted to 5687 and that 23,168 consultations were given at the surgery. With the exception of the little help which was obtained for the three-guinea fee all this work was done, or ought to have been done, by one single person. If all the patients were not seen by the solitary medical officer employed by this institution, then they must have been treated by an unqualified assistant, probably the dispenser of drugs. If we divide the £311 14*s.* 9*d.* paid for medical advice by the 28,855 visits and consultations given it will be seen that the medical officer received for each consultation or visit a munificent sum amounting to a fraction above 2½*d.* We have heard of shilling and even of sixpenny doctors, but here we have a 2½*d.* doctor.

Of course, if this was a work of charity there would be no reason to complain. Medical men are constantly attending the poor for nominal fees or gratuitously; but the members of this society would indignantly repudiate the idea that they were recipients of charity. Nor is there any reason for them to claim charitable help. No wage limit is imposed and many members are very well off, yet they do not scruple to pay only 4*s.* a year so as to secure the services of a fully-qualified practitioner when they are ill. Thus there is a tradesman, who sometimes employs as many as 100 men, who lives in a house for which he must pay some £60 a year, and yet he belongs to this society and is content to receive medical service at an average rate of about 2½*d.* per consultation. Another member keeps an establishment on such a large scale that the rent and taxes are estimated at £300 a year. Yet he only pays 4*s.* a year for medical attendance. That he could pay more is proved by the fact that his family do not care for the club medical man and when ill call in a private practitioner to whom they pay 5*s.* a visit. If some blunder in diagnosis or treatment should result these comparatively wealthy men will certainly only have themselves to blame. Even a fully-qualified practitioner cannot perform an impossible task and it is altogether beyond human capacity to give 28,855 careful consultations in the course of a single year. The society consists, or is supposed to consist, mainly of workmen and the workmen's ideal is an eight hours' day. But the medical officer's position, it will be seen, by the rate of pay he gets, is very inferior to that of his employers, the workmen. We will say, therefore, that he has to work ten hours a day for every day in the year, Sundays included. This makes 3650 hours in the twelve months. During that time he has to give 28,855 consultations. This means seven minutes for each consultation. But we must take into account that these consultations comprise 5687 visits paid to the patients in their own homes. If therefore from the seven minutes we deduct the time taken going from house to house—some of the houses are situated at a distance of three miles and no carriage is allowed—and if, further, we make some allowance for a partial rest on Sundays, it will be seen that barely more than a minute or two remains for ordinary consultations. As a matter of fact, the general opinion is that the medical officer did not see all these patients and did not give all these consultations, but many of them were seen by an unqualified assistant. One case was related to me concerning a member who was drawing sick pay and yet had never seen the medical officer, but only his unqualified assistant. As he did not get any better the member called in a private practitioner. The board of management took up this matter and finally paid the private practitioner's bill. Now, however, that unqualified assistants are no longer allowed it is proposed to increase the subscriptions and to employ a second medical officer to act as a qualified assistant. This is all the more necessary as the work is not limited to the care of patients. There are also medical examinations of persons who desire to join one of the amalgamated friendly societies. The medical examination is not instituted with the view of protecting the medical officer against the admission of unhealthy members. The relations of members are admitted to the medical department of the friendly societies' organisation without any medical examination, however delicate or ill they may be. It does not matter to the lay administrators of this society how much work the medical man has to do. But with regard to full members the matter is very different, because if they are ill they are entitled to draw a sick allowance, and that is why they must be medically examined and the medical man must certify that they have sound constitutions before they are admitted as full members. Thus the medical officer must do all he can to protect the society, while he is not allowed to do anything to protect himself.

Referring again to the published accounts, it will be seen that the dispenser's salary and that of his locum tenent amounted in all to £132 15*s.* 6*d.* The purchase of drugs and bottles cost £86 2*s.* 4*d.* Rent of the surgery, insurance, and taxes came to a total of £63 17*s.* 8*d.* Then there is a secretary, who draws a salary of £35, and there are fees to auditors, treasurer, &c.; total, £43 6*s.* Altogether the working expenses are put down at £675 18*s.* 11*d.*, of which the medical officer does not receive half. But the receipts are £100 in excess of this expenditure. This net profit is, of course, in the main due to the medical officer's work, yet he is allowed to have no share in the capital which he thus builds up.

Much as the commercial insurance companies may be decried the share they allow to their medical officers if honestly paid is much larger than that given by the friendly societies. The most important at Tunbridge Wells is the Liverpool Victoria Legal Company, and here it charges children as well as adults 1*d.* per week. Of this sum the insurance company only deducts 20 per cent. for its working expenses and for the collecting agents' commission. Unfortunately, the medical officer has no means of checking the list of members given him. The only way is to compare the card of the patient with the list, but then if there is an error it can only be found out when the patient is ill. This was done by one of the medical officers at Tunbridge Wells, and the errors were so obvious that in several cases they were acknowledged and the balance was paid. Whether such errors are due to the company or the company's canvasser it is difficult to say. The canvassers are constantly changed and mistakes might accidentally occur, but it would be very advantageous to put a smaller number of names on the list given to the medical man than are inscribed on the list kept by the canvasser. The chances of detection are small. If the persons whose names are omitted from the list given to the medical man do not fall ill the omission will pass unperceived. Nor is it likely that the medical officer, unless his suspicions have been aroused, will take the trouble to verify whether every patient who presents himself is on his list. But with regard to the list, such as it is, the medical officer is paid punctually and receives the full 80 per cent. of the subscriptions paid by the members inscribed on the list. It is true that he has to provide the drugs, but the working expenses are not increased by a charge for a dispenser's salary, for the rent and taxes of the dispensary and surgery, as is the case both with regard to the Provident Dispensary

Digitized by Google

and the Friendly Societies' Medical Association. On the other hand, these commercial insurance companies entirely ignore medical ethics. They canvass in all directions, pointing out the advantages of life insurance combined with medical insurance, praise their own medical men and abuse the other members of the profession. Of course, they have no notion of establishing a wage limit; and, on the contrary, prefer that their members should be well off as they are more secure in the receipt of the subscriptions. If one of their medical officers, being dissatisfied with this state of things, proposes to resign, the company will threaten to bring down a new practitioner to compete against him in his own district. There is also the Croydon and Surrey Insurance Company at Tunbridge Wells. This is very similar to the Liverpool Victoria Legal Company, but has not so many members.

Fortunately the members of the profession are commencing to make a stand against these abuses. The two consultants who were formerly attached to the Friendly Societies' Medical Association have resigned; and the question arises whether all the profession should not boycott this association and refuse to consult with its medical officer. Then, again, one of the local practitioners who had a very large number of members of the Liverpool Victoria Legal Company on his list has given them all up. This is the more remarkable as he had absolutely no complaint to make. He was paid punctually and he thought the terms of payment were on the whole fair. The greater part of his patients were exceedingly poor and it was a charity to help them. When, however, he discovered that any of his patients could afford to pay he struck them off his list and the Liverpool Victoria Legal Company did not object to this. But though he was thus able on various occasions to prevent abuse he could not prevent the canvassing. Several medical men in the town wrote to him saying that their patients had been canvassed by the agents of the company which employed him as their medical officer. He found also that his own private patients had likewise been canvassed and that patients who used to pay him the usual fees now proposed to give him only 1*d.* a week through the intermediary of the Liverpool Victoria Legal Company. At the same time he had read several articles on the "Battle of the Clubs" in THE LANCET and these helped to convince him that though personally he had no complaint to make, still the system was bad. He therefore resigned because he was anxious that there should be no stigma attached to his name. This certainly is a moral triumph. The idea that there is a stigma attached to those who sell their professional services to a speculating commercial company should be spread broadcast. This is a weapon held in the hands of the profession. Good use should be made of it.

THE PLAGUE IN VIENNA.

(BY TELEGRAPH FROM OUR OWN CORRESPONDENT.)

IN January, 1897, the Imperial Academy of Sciences of Vienna sent out a Commission to investigate the epidemic of plague in Bombay. The members of the Commission were Dr. Müller, a physician; Dr. Albrecht, an anatomist; Dr. Ghon, a bacteriologist; and Dr. Poech, physician's assistant who also has charge of the photographic department of the hospital. After a stay of three months they returned to Vienna and established a plague laboratory of their own in Professor Weichselbaum's pathological and anatomical institute in the General Hospital. Here they made pathological investigations of specimens which they had brought with them, obtained from fifty-two post-mortem examinations, observing the morphology and biology of the plague bacillus and making experiments on animals with a view to ascertaining the nature of its pathogenic action and the possibility of immunisation. On Oct. 15th a man named Barisch, who looked after the animals, suddenly fell ill with high fever and cough without expectoration. Dr. Stejskal, the assistant physician, diagnosed pneumonia, Dr. Ghon expressed his suspicion of plague, and the case was isolated in Dr. Nothnagel's clinic, where Dr. Müller and Dr. Nothnagel discountenanced the diagnosis of plague as there was no enlargement of the spleen. On Oct. 17th the patient's sputum contained blood, the microscope showed polymorphous bacilli, and a guinea-pig was inoculated with the sputum. On Oct. 18th the guinea-pig was killed, its glands were found to be enlarged, and the microscope showed plague bacilli. In the afternoon Barisch, whose symptoms included high fever and copious expectoration containing blood, became collapsed and died. A guinea-pig inoculated with blood from his heart died in two hours. Sputum collected on Oct. 17th gave plague bacilli on cultivation, as also did the glands of the guinea-pig. No post-mortem examination of Barisch was made on account of the risk of an extension of the disease, but the body was buried after Dr. Müller and two nurses had wrapped it in sheets impregnated with corrosive sublimate; they also cleansed the ward. On Oct. 20th Nurse Pecha, having fallen ill with fever, cough, and expectoration containing blood, was transferred to the Infectious Hospital under the care of Dr. Müller and the second nurse named Hochegger. Nurse Pecha's sputum contained bacilli. Dr. Müller began to feel ill. On Oct. 21st he suffered from fever accompanied by expectoration, and he found plague bacilli in his own sputum and also in Nurse Pecha's, whose temperature rose to 41° C. (105·8° F.). Dr. Poech undertook the treatment of the patients, and was treated prophylactically with Paltauf's serum, but Dr. Müller refused the serum treatment. On Oct. 22nd Dr. Müller showed typical pneumonia and he died on Oct. 23rd. As in Barisch's case no post-mortem examination was made. Nurse Pecha was suffering from continuous high fever. On Oct. 24th Dr. Marmorek arrived from Paris with a supply of Dr. Roux's serum, injections of which were given to Nurse Pecha and prophylactically to Dr. Poech and two nurses. On Oct. 25th Nurse Pecha's condition showed little change, if any, but on Oct. 26th she was described as moribund. As soon as the first case of plague was clearly recognised the Plague Commission permanently closed Professor Weichselbaum's Institute. All the animals used for experiments were killed, and the drains of the Institute were disinfected; Dr. Nothnagel's clinic was cleared and disinfected and the medical men and nurses belonging to it were isolated; the public were refused access to the General Hospital, all the medical men and the nursing staff were kept indoors, and some supposed febrile cases were transferred from the Institute and Professor Nothnagel's clinic to the Infectious Hospital. Barisch's wife and brother were also admitted to the Infectious Hospital and received prophylactic treatment. No one has been attacked with plague since Dr. Müller fell ill, and all the persons in isolation have remained free from it up to Oct. 26th, the symptoms which were regarded as doubtful being only those of sore-throat. On Oct. 26th Nurse Pecha's was the only case officially notified as plague in Vienna, though the symptoms of a companion nurse are gravely suspicious. She and those who had been in communication with her and all the suspected cases are completely isolated in the Infectious Hospital. Barisch probably received the infection by way of his respiratory organs while feeding the inoculated guinea-pigs; Dr. Müller and Nurse Pecha were obviously infected by inhaling the germs coughed up by Barisch. In all three cases the symptoms were exclusively pulmonary; glandular enlargements, which point to infection conveyed through the skin, did not occur. Infection never takes place by way of the alimentary canal. The nursing staff in the Infectious Hospital are provided with "bacteria filters" to protect them from inhaling bacteria.

NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT.)

Plague and Small-pox.—The Destruction of Rats.—Deaths of Medical Officers.—The Progress of the Plague.—A Plague Commission from England.

IT was recently asserted that animals which are susceptible to plague become immune if they be vaccinated with ordinary cow-pox in four different parts of the body. Whether this statement be founded on any experiments is not stated. One thing, however, is certain, that those persons who have been vaccinated have no protection from plague. There does not seem to be any antagonism between the toxins of these two diseases. There is no evidence either that those who have had small-pox are any safer against contracting plague. The idea was said to have been current in Constantinople when plague visited that city, but investigations made in the Byculla Jail at Bombay do not give it any support. There was found to be a marked similarity in the proportion of

Digitized by Google

attacks among the primarily vaccinated, amongst the re-vaccinated, and amongst those who had had small-pox.

There is reason to believe that the extermination of the rat population in a district bordering on a plague-infected area would have a preventive effect on the extension of this disease. So far the only attempt which has been made in this direction has been in the destruction of rats by the ordinary methods. It is now suggested that they should be infected with some disease. The problem, however, has been to find a specific infective disease which is pathogenic to rats but not to man. It is stated that some progress has recently been made in this direction. There is little doubt that plague primarily affects the rat and that it is through the rat that the disease spreads amongst men. Wherever an outbreak of plague has occurred amongst human beings it has almost invariably been preceded by plague among the rats. Although plague is not very infectious from one human being to another, except, perhaps, the pneumonic form, there is reason to believe that it is highly infectious among the rats. If, then, the rats could be exterminated in advance of the plague there would be great prospects of preventing the spread of the epidemic. The interval between two epidemics of plague seems to be about the time required to renew the rat population, and although the plague is very fatal and appears to kill off every rat, yet a few either survive the disease or fail to contract it, and these few soon regenerate the rat population. The conditions then become again favourable for a fresh outbreak and the cycle of disease incidence is again repeated. Some of the above facts, although repeatedly observed and recorded, have not been taken to heart by the plague authorities and regulations still continue to be issued as if an ordinary infectious disease, such as scarlet fever or measles, had to be dealt with. It is upon the basis of house contamination that the emptying or burning down of houses with the encampment of the inhabitants in the open country around has alone proved of real value.

I regret to hear that within a fortnight two of the medical officers of the Maratha Hospital in Bombay have been attacked with plague and that one has died. Neither of the officers lived in plague-infected localities, and the presumption is that they both contracted it at the hospital. The medical officers of this hospital are native practitioners. As well-ventilated, well-arranged, and well-conducted hospitals have hitherto been shown to be extraordinarily safe as regards contagion and infection of plague some inquiry should be instituted into this and some of the other native hospitals. Many of these hospitals are only converted houses and are ill adapted for the purposes in view. They are, moreover, situated in closed-in and very crowded localities.

The summary of the progress of plague during the week is not satisfactory. In the districts and states of the Bombay Presidency the reported number of plague cases rose from about 4100 to over 5000. It is said that in Dharwar the disease has become too prevalent for the staff to cope with, that corpses are being found in the outskirts of the town and fields with no one to bury them, and that they are obliged to be left as they are to decompose or to serve as food for the jackals and the vultures. The southern part of the Presidency is badly infected, the chief increase occurring in Dharwar, Belgaum, and the Satara district, and the Kolhapore State. Calcutta is apparently free and Karachi had only one death. The death-roll for Bombay city shows a terrible rise, the figures being 1002 or over 400 above the average. Probably the whole of this excess is due to plague, although the official returns give only 243 deaths from this disease.

It is understood that a Plague Commission will shortly be formed consisting of five members with a secretary. Three eminent medical men will be sent out from England.

Oct. 7th.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

The Need of a Physical Laboratory in University College, Liverpool.

THE need of a physical laboratory in University College has been felt for a considerable time, as the accommodation provided for the department of physics has become altogether too limited owing to its rapid development. To make use of Professor Lodge's own words, "it is becoming increasingly difficult to accommodate the ordinary student and will soon be impossible." In THE LANCET of Oct. 22nd reference was made to the munificent donations of Lord Derby and Mr. Ralph Brocklebank towards the erection of new buildings to comprise the departments of anatomy, medicine, and surgery, which are so urgently required. It is much to the credit of Professor Lodge that he willingly and approvingly waived his immediate claim to a new physical laboratory, believing that the wants of the above-mentioned departments were more pressing. In a letter to the local press on the need for a local physical laboratory Professor Lodge reviews the history of his department since his appointment as the first professor of physics eighteen years ago. The terms of the letter are temperate in the extreme, although showing a condition of things which cannot be allowed to continue much longer. He says that on his appointment he was introduced to the temporary accommodation which was to serve him as a laboratory both for teaching and research and which, he was told, was to satisfy him for twenty years. Professor Lodge truly points out that physical laboratories in this country and even on the continent and in America were not then what they are now. Twenty years makes a wonderful difference in a progressive subject in the Victorian era, and the whole idea of a working student's physical laboratory is quite recent, originating in a large measure with Lord Kelvin at Glasgow, who began in a dark hole where now is the old College-street railway station. The first practical class (one of 5 students only) which Professor Lodge had was conducted in an upper room of a building formerly used as a lunatic asylum, with the apparatus mostly on the floor. Gradually, as the other professors expanded into new buildings for their respective departments, the professor says, he also expanded by occupying their discarded rooms. He would be loth to leave them now, having in a manner grown into the place, but for two serious drawbacks—viz., want of cleanliness and unhealthiness. He cannot recommend advanced students or graduates of other universities to come and do research work at University College—there is literally no room. He dilates on the material scientific advantages to be met with at Berlin, Strasburg, Zurich, Harvard, and Baltimore and at other places far poorer and smaller than Liverpool. He goes so far as to say that really advanced students, even his own, must migrate elsewhere. The pinch is felt most by the more advanced students. With an average attendance of 26 or 27 students at the present time and these likely to increase as the session goes on, and in addition a few teachers only able to come on a Saturday and a large number of evening students on Thursdays, he wonders how they all get fitted in. And then over and above this number there are 77 first-year students to be put through a beginner's course of laboratory instruction. These have to be taken in batches; they cannot be taught nor can they be examined all at once or in two sets as in Manchester. At the electro-technical department the pressure is not so severe, but it, too, has to be carefully organised. Altogether Professor Lodge makes out a good case for new laboratories, and when that desired object has been attained there will be none more worthy and more pleased to perform the opening ceremony than that distinguished man of science, Lord Kelvin, who, on parting at the railway station with his host, Professor Lodge, on the occasion of his recent visit to Liverpool, made use of words to this effect: "When they give you a new laboratory I will come and open it. Not laying foundations, that's a dreary ceremony, but the real opening." All wish Lord Kelvin health and strength to enable him to fulfil his promise to Professor Lodge.

Opening of the Albert Infirmary, Winsford: The Duke of Westminster on Vaccination.

The Duke of Westminster performed the opening ceremony of the Albert Infirmary in Winsford on October 20th. The new infirmary is the gift of Mr. W. H. Verdin, D.L., for the benefit of the inhabitants of Winsford and Middlewich, and the surrounding districts. It was formerly the mansion of the Verdin family; and is a square stone-fronted building. On the ground floor are reception rooms, nurses' rooms, and convalescent rooms, and 2 men's wards with 8 beds. On the first floor are women's and children's wards which contain 4 beds. The new infirmary will be governed in conjunction with the Victoria Infirmary at Northwich under a board of management of which Sir Joseph Verdin, Bart., is

Digitized by Google

president. The Duke of Westminster, in the course of his opening speech, said that medical and surgical science had made very considerable strides in the direction of curing and preventing disease. He hoped that public opinion would be still more educated and directed to the advantage of preventing disease, of which they had heard a great deal lately in connexion with vaccination. He would that public opinion might arrive at the conclusion that vaccination was after all a specific for one of the most loathsome diseases to which the human race was subject. The Duke also alluded to the advance which had been made in nursing during the latter part of the present reign.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Edinburgh University: Sir Thomas Grainger Stewart's Inaugural Address to the Faculty of Medicine.

THE classes in the Faculties of Arts, Medicine, and Law in the University of Edinburgh opened on Oct. 18th, for the winter session. In some instances introductory lectures were delivered by the Professors; in others the work of the class was at once taken up. In opening the class of Medicine, Sir Thomas Grainger Stewart spoke of the reciprocal duties of the profession and of the community in reference to the arrest of such diseases as small-pox and phthisis. With reference to the New Vaccination Act, Sir Thomas Grainger Stewart congratulated his hearers that in Scotland the attitude of the people towards vaccination was the sensible and scientific one, while he stigmatised the action of the Government in introducing a conscience clause as "from a medical point of view absolutely disastrous folly." With regard to phthisis he asked his hearers to grasp the conception of the very dreadful fatality which tuberculous disease was causing in these days in that the mortality from tuberculous disease in our own and most countries was such that it accounted for one in every six of the deaths which occurred. Referring to preventive measures now being gradually taken against phthisis he wished his hearers to note the suggestions, which, in his opinion, were very important. They should attend to the education of the public, and especially of infected individuals and families, in regard to the laws of the spread of tubercle. They should make everybody know that a phthisical patient was a source of danger to those round about him unless proper precautions were taken. Precautions should be taken with regard to the quality of food and especially with regard to the quality of milk. Sir Thomas Grainger Stewart also thought that there should be compulsory notification of phthisis.

Glasgow University: an Emeute.

The session has opened in a very stormy and unfortunate manner. The new principal, according to the official intimation, was to signalise his accession to office by the delivery of an address to the students in the Bute Hall, and the eventful day found gathered together not only the academic dons but also the heads of the municipality and various representatives of learned bodies to do honour to the occasion. In the usual stately fashion the Senators entered in procession the Bute Hall and the new principal ascended the rostrum. But from the commencement it was evident that a very unruly spirit for some reason or other existed in the undergraduate breast. Noises and disturbances of all kinds greeted Dr. Story's appearance, and remonstrance was vain. In the end the Principal folded up his manuscript and followed by his colleagues left the hall. It is difficult to explain, and of course impossible to justify, the behaviour of the students. During his term of office as professor Dr. Story has on more than one occasion come into acute conflict with the student world; but these are for the most part old tales and scarcely have more than the interest of tradition for the students of to-day. Such traditions, however, are not unwelcome to those who believe it is their inalienable right to "kick up a row" whenever an occasion presents itself. It is not to be accepted that the uproar was part of a preconcerted scheme, and by this time the great majority of the undergraduates regret at least the extremity to which the demonstration was pushed. It was a silly exhibition of animal spirits and bad taste, and it is to be hoped that no more serious interpretation will be attached to it. The management of a large body of young men is not an art to be mastered in a day and possibly Dr. Story may be able to add to his undoubted capacity and courage that nameless quality which wins the good temper and sympathy of sound-hearted and demonstrative youth. Some wise words have been spoken by Professor Coats, to which the Senate no less than the students may well pay heed.

Glasgow Veterinary College.

The new session was opened on Oct. 21st by Dr. Lindsay Steven, who delivered an address on the Prevention of Tuberculosis, in which he advocated combined action on the part of the medical and veterinary professions. He believed compulsory notification of tubercle in man to be at present impossible; hospital treatment of pulmonary tuberculosis was, he contended, not curative, but by the provision of sanatoria in the country for early cases and by the distribution of handbills from house to house so as to secure popular instruction much could be done to prevent the spread of the disease. The veterinary practitioners, Dr. Steven pointed out, were in a fortunate position to check the very springs of the disease, as they were able by suitable measures to prevent the distribution to human beings of contaminated food supplies.

St. Mungo's College, Glasgow.

The medical session was opened on Oct. 20th by an address delivered by Professor Maitland Ramsay, M.D. Glasg.

University of Aberdeen.

The medical classes for the present winter session opened at Marischal College on Oct. 19th, the work being commenced by nearly all the professors without introductory remarks. In opening the class of materia medica Professor Cash, however, drew attention to the British Pharmacopœia of 1898, recently issued by the General Medical Council, as a somewhat conservative volume, neither omissions nor additions being of a prominent character. The metrical system, he observed, was introduced as an alternative to the old system for compounding, but an equivalent was not given, and unfortunately the decimal method was not recommended to the prescriber even as an alternative. This serious blemish, he added, it was to be hoped, would be rectified by the compilers of the next volume. In his introductory lecture on Oct. 20th to the pathology class Professor Hamilton referred to the transformations in Marischal College, the chief new feature this year being the completion of the south wing for the accommodation of the department of physics. Having remarked that Aberdeen was now one of the best equipped medical schools Professor Hamilton addressed himself to a comprehensive survey of new medical schools in England which threatened to prove dangerous rivals to those of Scotland. The new National Philosophy buildings at Marischal College were opened by Professor Niven, who gave an interesting address on the history of the teaching of the subject in the University. The new lecturers in history, education, and German language and literature were introduced to their respective classes by Principal Sir W. D. Geddes. There were 25 passes in the medical "preliminary" on this occasion; 8 candidates took part in the medical bursary competition.

Aberdeen Hospital for Sick Children.

The extension of this building—being a home for 30 nurses—has now been completed from designs by Mr. A. Marshall Mackenzie, A.R.S.A., architect, Aberdeen. It is a granite building consisting of ground floor and three floors above and includes dining-room, sitting-room, bedrooms, and sick-room. The extension has been plainly furnished and the total cost amounts to the wonderfully small sum of about £2000. A bazaar in aid of the hospital is to be opened in the Music Hall Buildings, Aberdeen, on Friday, Oct. 28th, by Princess Henry of Battenberg (Princess Beatrice), and on Saturday, Oct. 29th, by Lord Provost Mearns, Aberdeen.

Typhoid Fever in Aberdeen.

Dr. Matthew Hay, medical officer of health of Aberdeen, reports regarding the outbreak of typhoid fever in Aberdeen in the month of September that "typhoid fever shows a very large increase, 30 cases with 3 deaths having been reported, as against 6 cases with 1 death in the preceding month. This is by far the largest number reported in a single month for several years. The excess of cases was traced, as indicated in last month's report, to an infected milk-supply."

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The Regius Professor of Medicine in Dublin University.

SIR JOHN BANKS, K.C.B., has resigned the position of Regius Professor of Medicine in the University of Dublin. Sir Francis Cruise, consulting physician to the Mater Misericordiæ Hospital, and Dr. J. M. Finny, King's Professor of Medicine in the Medical School of Trinity College, are mentioned as candidates for the office.

Sir Patrick Dun's Hospital.

The opening meeting of the session was held at Sir Patrick Dun's Hospital on Oct. 19th, when Dr. C. B. Ball, Regius Professor of Surgery in the University of Dublin, delivered an inaugural address, dealing with the advances in surgery which had taken place during the last quarter of a century.

The Royal College of Surgeons in Ireland.

The President, Vice-President, and Council of the Royal College of Surgeons in Ireland have issued invitations in connexion with the formal presentations of medals and prizes which will take place on Nov. 1st. On that occasion the students of the medical school of the college to whom such honours were awarded at the termination of last session will receive them from the President.

Irish University Education.

The Lord Lieutenant of Ireland (Earl Cadogan) paid a State visit to Belfast on Oct. 18th and laid the foundation-stone of the new city hall and opened the newly-erected electric lighting station. He was subsequently entertained at a sumptuous luncheon by the Lord Mayor (Alderman Henderson, M.A.), when, in the presence of 400 of the most influential citizens of Belfast and Ulster, he delivered an address, in response to the toast of his health, dealing among other matters with university education. His Excellency stated that for some years past he had sympathised entirely with the views of Mr. Arthur Balfour on this question. He said he could not hope to receive any enthusiastic support for that view. Mr. Balfour had stated that nothing but the education of his party could possibly bring his ideas to realisation. He (the Lord Lieutenant) said if the party could be so educated then a way might be found out of the difficulty. This remarkable and pointed reference by Lord Cadogan to the subject of a Roman Catholic university has, as might be expected, aroused a great deal of discussion and the general feeling is that the question of Irish university education is again thrown into the melting-pot. THE LANCET is not the place in which to discuss political or religious questions, but one thing is clear: if the Government decide to found a Roman Catholic university there is no longer any reason for the existence of the present Royal University, and where are the northern students, who constitute over 50 per cent. of those who go to the Royal University, to obtain degrees? The Lord Lieutenant did not allude to this point and it is one which the Government must fully consider in any new settlement of Irish university education. There can be no question that the present condition of Irish university education is most unsatisfactory. No one is content with it. But when it is remembered that in dealing with such a subject Mr. Gladstone shipwrecked his Government, many fear that it may form the grave of the present political party in office, unless, as some suggest, the whole question is to be taken up and an attempt made to settle it on non-party lines by representatives of both sides who do not sit on either of the front benches in the House of Commons.

Belfast Corporation.

On Oct. 19th a special meeting of the corporation in committee was engaged for a lengthened period in considering the character and contents of a new Bill which it is proposed to promote in the next session of Parliament. A great many matters considered by committees and by private members to be of sufficient importance to apply to Parliament for power to deal with were discussed, and amongst others that of the compulsory provision of water-closets in all houses at present furnished only with privies and to lend money to owners of property to assist them to carry out this object. A very influential deputation, of which Dr. W. A. McKeown was the spokesman, appeared before the council on the same date, arguing the chief objections to the continuance of the traffic through the city of traction engines and their accompanying waggons. Dr. McKeown pointed out that these objections were: excessive noise; vibration; damage to sewer- and water-pipes by the passing of the heavily-laden waggons, breaches in sewers being caused in this way and the ground being impregnated by means of the leakage with objectionable material frequently charged with germs of typhoid; the damage to property, house-walls being cracked and great difficulty being experienced in tracing the damage to the traction engines owing to the non-appearance of external signs till perhaps days after the harm had been done; and the inability to obtain satisfaction from the owners of these engines when they are known. The Lord Mayor stated that in the preliminary report submitted to the corporation concerning the new measure there were these words, "To abolish goods traction-engines travelling in the city." With this statement the deputation were quite content.

The Health of Belfast.

The death-rate of Belfast for the week ended Oct. 15th from all causes was 27·9 and from the principal zymotic diseases 7·0. The number of cases of typhoid fever notified was 149 during the same period, in the previous six weeks the numbers having beeen 157, 172, 164, 247, 170, and 271 respectively. These figures show that there is little change during the past two weeks in the number of cases of typhoid fever notified and would seem to indicate that the recent outbreak or recrudescence of the disease is passing over and that we are reaching the normal endemic condition of typhoid fever in Belfast. Dr. Lorrain Smith, who has been investigating the problem of the causation of the typhoid fever in Belfast, has reported to the Public Health Committee that since the beginning of September he had given his whole attention to the investigation of the cause of the epidemic; that in the course of the work many side questions had arisen which required solution; and that the whole problem had assumed a form which in the first instance he did not anticipate, and on this account he was not yet in a position to come to a definite conclusion, but he had confidence that the methods on which he was working would yield decisive results. A curious point, which may lead to further complications, arose at the last meeting of the Public Health Committee in reference to a letter received from the board of guardians. In this communication it is suggested that the Belfast Corporation should contribute a moiety of the cost of the cleansing of the Holywood foreshore of the decomposed seaweed impregnated with sewage matter which has accumulated there and which the guardians are having removed at a cost of about £100. Holywood is a small town situated on the right hand side of Belfast Lough, about five miles from the city, and the interesting point is that the guardians evidently believe that the pollution of the shore there is due to the fact that owing to the plan of the main drainage scheme of Belfast the sewage of that city is spread out on each side of the Lough, and so Holywood is injured. The Public Health Committee decline to fall in with the suggestion of the guardians on the ground that the sewage of Holywood itself, as well as that of the new adjacent military barracks, is, with the cognisance of the board of guardians, discharged on to the Holywood foreshore. There is no doubt that some contamination may arise in this way, but there can be no question that Belfast is the main cause of the horrible stenches which exist at times on both sides of the Lough, and which it is feared will lead to further depreciation of property unless the main drainage scheme of that city is completely reorganised, a work which will be as formidable as it will be expensive. The truth is, that the city of Belfast has completely outgrown the schome which is at present in service for carrying away its sewage.

The Belfast Hospital for Sick Children.

At a special meeting of the governors of this hospital, held on Oct. 24th, Dr. Robert Campbell was promoted to the post of surgeon, in place of Dr. J. S. Morrow, retired, and to the office of assistant surgeon thus created Dr. Andrew Fullerton was elected by a very large majority.

The Ambulance Branch of the Belfast Fire Brigade.

During the year ended June, 1898, the most efficient ambulance service of the Belfast Fire Brigade received 1643 calls (an increase of 368 on the previous twelve months), and the department, which is worked entirely by the fire brigade

Digitized by Google

staff, responded to 1630 calls (being unable on 13 occasions to do so owing to the staff being engaged at fires), occupying 741 hours 51 minutes (being an increase of 112 hours 21 minutes from last year), showing an average of 27 minutes per journey from the receipt of the call until the carriage returned to its station. The distance travelled was 4226½ miles, or an average of 2½ miles per single journey. It is probable that when a divisional station is erected at Ardoyne a second ambulance will be placed there. This ambulance service, which is of the utmost value in a great commercial city like Belfast, is most admirably worked under the superintendence of Mr. Parker, chief of the Fire Brigade; and Deputy Commissioner Major Charles J. Trimble, L.R.C.S. Irel., who recently inspected the service on behalf of the St. John Ambulance Association, in his report stated that "so far as the general efficiency and usefulness were concerned the Belfast division is far ahead of anything I have yet seen. The members are firemen and certainly a more thoroughly efficient ambulance organisation no town or city could possess, the staff being always ready by night and by day to start at a second's notice on ambulance or transport duty." The city corporation deserves the utmost credit in having selected in Mr. Parker a chief who has completely reorganised their fire brigade and who has established an ambulance service which is now admitted to be one of the finest in the world.

Oct. 25th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The Surgical Congress.

THIS Congress came to an end on Oct. 22nd, the last meeting being devoted to the subject of Gynæcology and an exhibition of Instruments and Apparatus. A long discussion arose upon the technique of, and indications for, the operation of total abdominal hysterectomy. Before separating the Congress arranged its organisation for next year. M. Lucas Championnière was unanimously elected Vice-President for 1899 and therefore will be President in 1900, in which year the foreign sovereigns will be received. The evening of the last day was devoted to a *soirée* at the Hôtel des Sociétés Savantes, where a demonstration was given, arranged by Dr. Doyen, of cinematograph views of various operations performed by himself, such as craniectomy, resection of the knee-joint, hysterectomy, and others. The audience was very large and the apparatus worked most successfully, as there was much more electricity available than on Oct. 17th. It was derived from 40 large accumulators supplied by Dr. Doyen on finding that the ordinary street mains did not supply sufficient energy. *A propos* of Dr. Doyen he has just published in the *Revue de Gynécologie* for Oct. 19th a very strong letter addressed to every medical man in France as an answer to one published by M. Tuffier, in which the latter described as his own personal invention the method of arresting hæmorrhage by crushing the vessels with a strong pair of forceps. Dr. Doyen maintains that this instrument is but a modification of his vasiotribe and energetically maintains his right of priority to both method and instrument, for he had made M. Tuffier acquainted with both in the course of conversation. M. Tuffier, he says, has only made one alteration in his (Dr. Doyen's) method and that for the worse—namely, that he has given up the ligature after the crushing. M. Tuffier has announced a reply to be published in the next issue of the *Revue*, which will appear in two months' time.

The Congress of Urology.

The third Congress of Urology held in France met this year from Oct. 20th to Oct. 22nd under Professor Guyon as President, who was attended by many of his pupils, and a large number of provincial specialists and surgeons who came to Paris to take part in the meetings of the Surgical Congress also attended the Congress of Urology. The chief matter for debate was the subject of vesical infection. It was opened by a report of researches by MM. Albarran, Halle, and Legrain. In reply MM. Bazy, Jules Janet, Dessus, and others spoke. M. Jules Janet proved that certain vesical infections were due to venereal disease. On the morning of Oct. 22nd the members of the Congress visited the wards set apart for genito-urinary complaints a the Necker Hospital.

The Library of the Faculty of Medicine.

The Faculty of Medicine has just taken a step which has called forth the most lively protestations from the medical men of Paris. The universities have recently acquired the right of receiving donations and legacies and of applying these to their own liking without any outside control and naturally they have taken advantage of this new privilege. The Government has, of course, reduced these new rights to as small a compass as possible and has laid down that any moneys received in future shall be devoted to the fitting up or improvement of laboratories, libraries, or buildings. The various faculties, however, can only raise money in new ways by taxing the students, a class who already pay sufficiently heavily, and the Faculty of Medicine has therefore decided that from Nov. 16th admission to the library will be no longer free, but that every reader will have to buy an annual card of admission which will cost 30 francs. This rule has met with universal disapproval. The new tax will bring in very little, for all *bonâ-fide* students whose names are entered at the Faculty will be exempt by reason of the fees they already pay to the University. The rule will, however, fall hardly upon men already in practice who frequently wish to consult the library for reference. On the other hand, as the rules state that anyone working in a university laboratory can consult the library on the recommendation of a professor it is evident that the monetary gains of the faculty will be very small in proportion to the annoyance inflicted upon the class affected. All the medical press joins in protesting against the new arrangement, and the very students, unaffected as they are by the new regulation, are organising demonstrations against it.

The Orthopædic Institute of Lille.

A scandal has just come to light in connexion with the Catholic Faculty of Lille. One of the professors, a distinguished surgeon named Guermonprez, accepted the post of director of an institution called the Orthopædic Institute, in which a priest, the Abbé Crud, treats patients without having a medical qualification. This priest, who was formerly the Curé of Sens, has carried on for a long time the trade of a bone-setter; he has been many times convicted for illegally practising medicine, and finally he fell under the condemnation of his religious superiors. He then left Sens and came to Lille, where some charitable and wealthy persons, believing that they were doing good, built a large hospital for him at Cantelen, whereby he was enabled openly to carry on his illegal medical practice. In order to protect himself from renewed convictions the Abbé managed to get a medical man to cover him, and this medical man was Professor Guermonprez. When the committee of the new hospital made use of Professor Guermonprez's name as a "draw" the Catholic Faculty of Lille publicly repudiated having anything to do with the Orthopædic Institute in a letter signed by the Dean (Dr. Desplats) and inserted in all the Lille papers. M. Guermonprez has sent in his resignation as Professor at the Faculty.

The Accounts of the Assistance Publique.

M. Napias, the director of the Assistance Publique, has just issued a balance-sheet together with a budget for 1899. The situation is far from satisfactory. The total sum at the service of the Assistance Publique, excepting a sum reserved for certain charitable institutions, is 14,588,932 francs, and this sum is entirely used up in the annual expenses of the *service*. Besides this sum the administration possesses certain *capitaux disponibles* and a reserve fund. The former sum amounted last year to 708,359 francs arising from sums paid by patients for their keep in asylums, from the sale of timber belonging to the Assistance, and from the sale of certain other articles. This sum, however, is entirely given up to the liquidation of certain expenses incurred previously. The reserve fund, which was constituted by the regulations of 1858, is provided for by taxing all the landed property of the Assistance in the sum of 10 per cent. and is intended to meet any unforeseen catastrophe, such as fire or a fall in the value of money. This sum, however, has been gradually diminished, not by fires, but by being applied to the purposes of other departments, and now only amounts to 12,527,718 francs. The new organisation for dealing with tuberculosis has absorbed 6,000,000 francs; the construction of children's hospitals, 833,400 francs; precautions against fire, 250,000 francs; surrender of certain sources of income, 900,577 francs. Moreover, the payment of the deficit standing over from 1897 will absorb 812,547 francs,

Digitized by Google

and the liquidation of a special debt owing to the Hôtel Dieu 779,341 francs. Bad debts are estimated at 231,661 francs, and finally the accounts for 1898 will probably show a deficit of 1,000,000 francs, so that the reserve fund will be still further reduced to 1,720,065 francs. This lamentable state of affairs is not improved by the fact that in the budget for 1899 the proposed payments to the medical staff are 1,213,028 francs instead of 1,151,488 francs in 1898.

Oct. 25th.

ROME.

(FROM OUR OWN CORRESPONDENT.)

Death of a Great Surgeon.

ITALIAN surgery has of late years progressed conspicuously, mainly from its adoption of the antiseptic therapeutics and the tidiness, not to say cleanliness, they imply. Formerly the mortality consequent on its intervention was out of all proportion to the skill in diagnosis and the manual dexterity it evinced. Excellent anatomists and "artists with the knife," the surgeons of Italy had too often the chagrin of seeing all their professional insight and "assured boldness" frustrated by sequelæ due to slovenliness in treatment. Thanks to "Listerism," however, all this is changed, at least in the great centres of the healing art—nowhere, indeed, more strikingly than in the clinique of Dr. Azzio Caselli, professor of operative surgery in the University of Genoa. He was a man, whether as a teacher, an operator, a consultant, or a citizen, whom Italy could ill spare; but now—such has of late been her evil fortune—he has gone to swell the list of her prematurely "lost leaders," having succumbed to a lingering and intractable disease at the early age of fifty-one years. Azzio Caselli inherited an honoured name in surgery, his great-grandfather, his grandfather, and his father having each been distinguished in the art as well as known to fame far beyond their native Reggio Emilia. There he himself was born in 1847, and thence with a view to the medical career he proceeded as a student to the University of Bologna. From that seat of learning he passed to Naples, where he became a pupil of the eminent surgeon Rizzoli, who quickly discerned in him the makings of a sound and self-reliant operator. Graduating at the age of twenty-two years he was first called to fill the post of *chirurgo primario* in the hospital at Reggio, and in that capacity laid the foundation of the esteem in which he was held in France, Germany, Austria, Hungary, and the British Isles. He created at Reggio the "Museo di Anatomia Patalogica," which even yet rewards a visit by reason of not a few of its remarkable preparations and which forms a kind of running commentary on the many brilliant operations he performed between his twenty-fifth and thirtieth year. As a teacher, moreover, he was careful to insist on "guiding principles" amid the details which, in their sheer multitude, are so apt to bewilder; and many were the ingenious and memorable generalisations of his which helped the student to a mastery of his subject in theory and in practice. In 1882 his reputation, by this time securely established, led to his appointment to the Professorship of Clinical Surgery in the University of Genoa, a post he held with increasing popularity till his death on Oct. 19th. Keeping pace with all the resources of the modern school, when, indeed, he did not contribute others of his own, he made his clinique the resort of ardent young aspirants to the surgical career from the remotest corners of the kingdom. Operations apparently hopeless seemed to turn out well in his hands, imparting the lesson so useful in these days, especially to Italians, "never to despair of the healing art." In laparotomy, in thoracic and in cerebral surgery, his results were generally as gratifying as they were encouraging and stimulating—indeed, those of Billroth, his lifelong friend, had scarcely a more inspiring effect on pupil and colleague alike. Add to this a nature finely "touched to the issues" of art and literature, a sense of citizenship which fructified in many an act of public philanthropy, a power to make and to keep friends in all ranks of life and under every variat on of circumstance, and the outside world will have some appreciation of the feeling of loss which in the week now closing accompanied Azzio Caselli to the grave.

Oct 21st.

Medical News.

SOCIETY OF APOTHECARIES OF LONDON.—In October the following candidates passed in the undermentioned subjects:—

Surgery.—F. Ede, Royal Free Hospital; L. Liebster, Vienna; W. M McLoughlin, University College Hospital; A. H. Priestley, Manchester; and W. R. Wilson, Dublin and Belfast.

Medicine.—C. G. Catterall (Section II.), Leeds and Westminster Hospital; H. Clough, Leeds; H. H. Cotman (Section II.), Aberdeen and London Hospital; H. L. Hands, Madras and Charing-cross Hospital; A. H. Priestley and S. Sugden, Manchester; and A. F. Weston (Section I.) and R. Le G. Worsley (Section II.), St. George's Hospital.

Forensic Medicine.—G. F. M. Clarke, Charing Cross Hospital; H. Clough, Leeds; P. T. Goodman, St. Thomas's Hospital; H. L. Hands, Madras and Charing Cross Hospital; P. A. Pierre, Westminster Hospital; A. H. Priestley, Manchester; and A. F. Weston, St. George's Hospital.

Midwifery.—A. G. C. Davies, Guy's Hospital; G. W. H. Edgelow, London Hospital; F. Golding-Bird, Guy's Hospital; F. S. Leech, University College Hospital; D. V. Lowndes, Westminster Hospital; R. R. Mowll, King's College Hospital; H. J. Pickering, St. Bartholomew's Hospital; P. A. Pierre, Westminster Hospital; and A. H. Priestley, Manchester.

The diploma of the Society was granted to the following candidates, entitling them to practise Medicine, Surgery, and Midwifery:—G. F. M. Clarke, F. Ede, A. H. Priestley, and W. R. Wilson.

CAMBRIDGE UNIVERSITY.—At the examination in Sanitary Science held in October, 1898, the following candidates satisfied the examiners in both parts of the examination:—

Lewis Potter Black, Thomas Carr, John Inglis Cook, Mohan Lal Dhingra, Alexander Duncan, Herbert Edward Goulden, John Knight, Campbell Samson Marshall, John E. O'Connor, Patrick Wilkins O'Gorman, Alfred Gervase Penny, John Alfred Knowles Renshaw, Joshua James Taylor, and Joseph Henry Whitaker.

Matriculation took place on Oct. 21st, when 897 freshmen inscribed their names on the University books. Of these 19 were post-graduate students from other universities. Dr. Langley, Lecturer in Physiology, has been elected a member of the Council of the Senate in place of Principal Glazebrook, now of Liverpool. Dr. Barclay-Smith and Professor D. J. Cunningham of Dublin have been appointed Examiners in Anatomy; Dr. H. K. Anderson and Dr. Starling of Guy's Hospital, Examiners in Physiology; and Mr. Ivatt and Mr. Easterfield, Examiners in Pharmaceutical Chemistry, for the second M.B. examination.

FOREIGN UNIVERSITY INTELLIGENCE.—*Munich:* A new Dental Institute has been established, to the charge of which Dr. P. J. Berten of Würzburg has been appointed with the rank of Extraordinary Professor.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. Heinrich Spöndli, formerly Professor of Midwifery in the University of Zürich, at the age of seventy-four years. He had been for many years in retirement.—Dr. A. Morrison, formerly Professor of Physiology in the University of Nashville.—Dr. K. F. Slaviansky, Professor of Clinical Gynæcology in the Military Medical School of St. Petersburg.—Dr. D. Kochs, *privat-docent* of Physiology in the University of Bonn.—Dr. Subbotin, Professor of Hygiene in the University of Kieff.

PRESENTATIONS TO MEDICAL MEN.—On Oct. 11th at the wardroom mess of H.M.S. *Cambridge*, the President presented Surgeon Leo Edward James, L.R.C.P. Lond., M.R.C.S. Eng., R.N., with a pipe and tobacco-pouch, together with a purse of money subscribed for by a large number of friends, on the occasion of his departure from the vessel.—Mr. W. G. Grace, L.R.C.P. Edin., M.R.C.S. Eng., celebrated the twenty-fifth anniversary of his wedding on Oct. 9th and received numerous presents, amongst them being a silver tea service and silver salver suitably inscribed from the professional cricketers of the Gloucestershire Cricket Club. — On Oct. 14th, in the board-room of the Great North of Scotland Railway Company's offices, on the presentation of the prizes won last session by those who attended the various ambulance classes in connexion with the railway—viz., Great North of Scotland, North British, and Caledonian and Joint Station classes—Mr. T. W. Ogilvie, M.B. Aberd., of Aberdeen, was the recipient of a set of medical volumes as a mark of appreciation of his services. The first volume bore the following inscription:—"Presented to Dr. Ogilvie, along with other 28 volumes, from the members of the

Digitized by Google

railway ambulance class, 1898, as a mark of their appreciation."—The mayor, corporation, and officials of Kingston-upon-Thames presented Dr. W. E. St. L. Finny with an electric pedestal lamp and shade on St. Luke's Day, which was also the eve of his wedding. At the same time they selected Dr. Finny as the mayor-elect for Kingston for the coming year.

THE LATE MR. LLEWELLYN COUCH.—Much sympathy is felt in Swansea for Mr. James Couch, M.R.C.S., whose son, Mr. Llewellyn Couch, was lost in the wreck of the Atlantic liner *Mohegan* on Oct. 14th. Mr. L. Couch was chief mate of the unfortunate vessel and was described by one of the survivors as undoubtedly the pluckiest man on board; it was certainly through him that so many lives were saved.

CHIPPENHAM COTTAGE HOSPITAL.—This hospital, the foundation-stone of which was laid on Nov. 8th, 1897, is now completed, and a meeting was held last week to appoint a committee of management, &c. Sir J. Dickson Poynder was chosen President, and amongst the managing committee Dr. W. T. Briscoe, Mr. M. S. Wilson, M.R.C.S. and Dr. Carter were elected as honorary members. Mr. F. K. Green, F.R.C.S. Eng., of Bath, was appointed honorary consulting surgeon.

THE LATE MR. EDWARD BARBER.—Mr. Barber of Glossop-road, Sheffield, who has just died in his sixtieth year, was a well-known practitioner in that city, and enjoyed much popularity among an extensive circle of friends. His professional education was received at the Sheffield Medical School and in London at St. Mary's Hospital. In 1874 he took the diploma of L.S.A., followed in 1877 by that of L.R.C.P. Edin. He settled in practice about twenty-five years ago in Division-street, and had been in Glossop-road since 1878. Mr. Barber was a Churchman and a prominent supporter of parochial organisations, but notwithstanding his large practice he was not connected with any medical institution beyond his membership of the Sheffield Medico-Chirurgical Society.

THE PLAGUE IN INDIA.—The plague returns for the week ending Oct. 22nd show a marked decline as regards Bombay city, the deaths reported being considerably less than in the preceding week. In the other districts of the Bombay Presidency, however, the deaths reported numbered 4700, being somewhat greater than in the preceding week, the greatest mortality being at Dharwar, Belgaum, and Satara. The disease continues to increase steadily in Bangalore city and at the military station. There is a slight increase, also, in the Madras Province, while numerous cases have been reported in Hyderabad State. One death has occurred at Karachi. Northern India is free from plague. The services of Lieutenant Chitale, I.M.S., have been lent for temporary plague duty at Belgaum.

Syphilitic) in a Boy aged thirteen years.—Dr. H. M. Fletcher: Viscera from a Case of Congenital Syphilis.—Prof. Curnow: Acromegalic (?) Skull.—Dr. H. Walsham: Epithelial Pearls in the Tonsil.—Dr. A. C. Latham: Multiple Dermoids in the Abdomen.—Dr. Rolleston: Idiopathic Hypertrophy of the Œsophagus. Card Specimens by Dr. N. Dalton (Dextrocardia with Left Superior Vena Cava), Dr. H. M. Fletcher (Excessive Dilatation of the Left Auricle), and Dr. T. Churton.

WEDNESDAY (2nd). — OBSTETRICAL SOCIETY OF LONDON. — 8 P.M. Specimens will be shown by Mr. Doran, Mr. Butler-Smythe, and others. Papers:—Mr. B. Sutton: (1) On a Case of Tubo-abdominal Pregnancy in which a Living Fœtus was extracted by Cœliotomy after Term and the Mother's Life Preserved; (2) On some Cases of Tubal Pregnancy.

THURSDAY (3rd).—HARVEIAN SOCIETY OF LONDON (Stafford Rooms, Titchbourne-street, Edgware-road).—8.30 P.M. Dr. S. Phillips: The Treatment of Typhoid Fever.—Mr. W. H. Battle: Cases of Intestinal Obstruction.

FRIDAY (4th).—CHARITY ORGANISATION SOCIETY (Portman Rooms, Baker-street, W.).—4.30 P.M. Dr. C. Dent: The Hospital. (Course of Lectures on Medical Relief.)

WEST KENT MEDICO-CHIRURGICAL SOCIETY (Royal Kent Dispensary, Greenwich-road, S.E.).—7.30 P.M. Council Meeting. 8 P.M. Special General Meeting. 8.15 P.M. Dr. G. Herschell: Constipation and its Modern Treatment.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY (West London Hospital, Hammersmith, W.).—8.30 P.M. Dr. F. J. McCann: Cases Illustrating the Difficulties in the Diagnosis of Early Tubal Pregnancy.—Dr. A. W. Addinsell: Parotitis following Ovariotomy.—Mr. R. Lake: The Treatment of Laryngeal Phthisis.

LARYNGOLOGICAL SOCIETY OF LONDON (20, Hanover-square, W.).—5 P.M. Cases and Specimens will be shown by Prof. Massei, Dr. D. Grant, Dr. St. C. Thomson, Dr. B. Baron, Dr. Pegler, Dr. W. Williams, Dr. Bond, Dr. Waggett, Mr. Lake, Mr. C. Symonds, Mr. De Santi, and Mr. Agar.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

MONDAY (31st).—LONDON POST-GRADUATE COURSE.—London Throat Hospital, Gt. Portland-st., W., 8 P.M., Mr. G. C. Wilkin: Anatomy of Ear, Illustrated with lantern.

TUESDAY (1st).—NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC (Queen-square, W.C.).—3.30 P.M. Dr. Tooth: Spinal Cord Localisation (lantern demonstration).

LONDON POST-GRADUATE COURSE.—Hospital for Skin Diseases, Blackfriars, 4.30 P.M., Dr. P. Abraham: Ringworm and Favus.—Bethlem Hospital, 2 P.M., Dr. Craig: Delusional Insanity; Paranoia.

WEST-END HOSPITAL FOR DISEASES OF THE NERVOUS SYSTEM (73, Welbeck-street, W.).—4 P.M. Dr. H. Campbell: Cases of Hypochondriasis and Allied Affections.

WEDNESDAY (2nd). — LONDON POST-GRADUATE COURSE. — Parkes Museum, Margaret-st., W., 4.30 P.M., Prof. A. Wynter Blyth: Sources of Water.

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST (Brompton),—4 P.M. Dr. Maguire: Anæmic Murmurs.

WEST LONDON POST-GRADUATE COURSE (West London Hospital, W.).—5 P.M. Mr. L. A. Bidwell: The Application of Splints to the Upper Extremity.

THURSDAY (3rd). — LONDON POST-GRADUATE COURSE. — Central London Sick Asylum Cleveland-st., W., 5.30 P.M., Dr. P. Manson: Clinical Lecture.

THE HOSPITAL FOR SICK CHILDREN (Gt. Ormond-street, W.C.).—4 P.M. Mr. Gunn: Demonstration of Ophthalmic Cases.

LONDON TEMPERANCE HOSPITAL.—2 P.M. Dr. S. Fenwick: Clinical and Pathological Demonstration to Senior Students.

CHARING-CROSS HOSPITAL.—4 P.M. Mr. S. Boyd: Demonstration of Surgical Cases. (Post-Graduate Class.)

FRIDAY (4th).—LONDON POST-GRADUATE COURSE.—King's College, 3 to 5 P.M., Prof. Crookshank: Tuberculosis and Leprosy.

WEST LONDON POST-GRADUATE COURSE (West London Hospital, W.).—5 P.M. Dr. G. L. Cheatle: The Application of Splints to the Lower Extremity.

Notes, Short Comments, and Answers to Correspondents.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only, AND, WHEN ACCOMPANIED BY BLOCKS, IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

TYPEWRITING *v.* PENMANSHIP.

WRITING in the *Journal d'Hygiène* (No. 1138, July 14th, 1898, p. 331) Dr. Moreau, of Tours, draws attention to what he qualifies as a remarkable work by Dr. Bizzorero on the advantages which typewriting possesses over the old-fashioned method of communicating ideas to paper. In the opinion of the author penmanship is fraught with danger to the writer's health in a variety of ways. To begin with, the constrained attitude he is compelled to assume favours a distorted spine, and especially scoliosis, together with venous congestion, headache, epistaxis, dyspnœa, and compression of the abdominal organs leading to constipation and dyspepsia, the latter disability being well-nigh inevitable should he sit down to write immediately after meals. The hands having to execute dissimilar work the penman cannot guide his pen without keeping his eyes glued to its point, and so his vision is bound to suffer, asthenopia being a frequent sequela owing to the straining of the accommodatory apparatus. In adults vertigo and vomiting frequently complicate the case, but in children, whose power of accommodation is greater, the complication to be feared is myopia. The use of a typewriter according to Dr. Bizzorero, is a perfect remedy for all these evils, and for the following reason. The operator sits straight, with head erect and arms at liberty. His lungs have free play, and his abdominal viscera remain uncompressed. His eyes undergo no strain, for he is not obliged to keep them fixed on a moving pen—in fact, after a little practice he can turn them away from the keys whenever he likes without interrupting his work. That distressing complaint, writers' cramp, so common among people who have to live by their pens, has no terrors for the typewriter. His occupation is an amusement to him, and without the least discomfort he can return to it immediately after eating. But it is not to the healthy alone that typewriting presents so many advantages. Numbers of people who have the misfortune to be palsied cannot use a pen, whereas they can express themselves freely, thanks to the machine; and many sufferers from conjunctivitis, iritis, or choroiditis who have been forbidden to

Digitized by Google

write after the old-fashioned style can in the same way carry on correspondence with their friends at a distance. If proof were wanting that typewriting has no injurious effect on the eyes it would be forthcoming in the fact that the blind readily become expert manipulators. Dr. Bizzorero advances rapidity in writing as a hygienic advantage, but the legitimacy of the claim is not very apparent. His contention in favour of legibility is, however, more likely to find acceptance, for in truth there are many handwritings of which the attempted deciphering cannot but be highly injurious to the health of the unfortunate persons whose sad fate it is to endeavour to interpret the hieroglyphics. Dr. Moreau observes, in conclusion, that the knell of dactylography is not likely to be heard for some time to come. Bookkeeping will no doubt long serve the cause of penmanship and what writer of *billets doux* would entrust his lucubrations to a mechanical typewriter!

DAVOS-PLATZ.

To the Editors of THE LANCET.

SIRS,—I am shortly proceeding to Davos-Platz in charge of two or three youths whose health is in some need of restoration and medical guidance. I think that perhaps the knowledge of this may prove useful to some of my brother practitioners, many of whom doubtless have cases which under medical supervision might likewise benefit from the salubrious conditions generally under which life in that more or less aseptic region is conducted. I may add that my young companions are in no sense invalids, but it has been deemed prudent as an extreme measure of safety to expose them through the coming winter months to the pure dry air and brilliant sunshine so constantly associated with this health-giving valley of the Alps.

I am, Sirs, yours faithfully,

JAS. T. JONES.

17, Mornington-crescent, Regent's-park, N.W., Oct. 12th, 1898.

MUNICIPALITIES AND THE HOUSING OF THE PEOPLE.

AT the opening of the commissions for the county and city of Dublin on Oct. 18th Mr. Justice O'Brien in addressing the city grand jury made some weighty remarks which deserve to be studied by the so-called "advanced" school of reformers. Much had been heard lately, he said, about the high mortality prevalent in Dublin and about the domestic circumstances of the humbler classes of the community who in too many instances lived under conditions incompatible with health and decency. The cause of the evil was alleged to be the character of the dwellings of the poor in the city, and the corporation had been severely blamed for permitting such a state of things to exist. He had to inform them, however, that many of those evils in their new structures were such as, with the limited powers of the corporation, they had no means of removing. The corporation were bound to exercise the functions assigned to them by law as far as possible to conduce to the sanitary state of the capital over which they presided, but their powers were limited to that function. The poverty which was prevalent in Dublin was the real and true cause of the state of things which led up to the insanitary dwellings and the high death-rate. With respect to the accommodation of the poor the corporation possessed certain powers of interference under the Sanitary Acts, but these powers must be exercised with discretion because no new houses adapted to the requirements of the humbler classes were being built, and of course poor people must live somewhere. In some towns the duty of providing the poor with suitable dwellings had been assumed by the municipal body, but with such a degree of discouragement as not to lead to the example being followed. Private enterprise would probably find that the erection of buildings suitable for the poor would be a profitable investment of money, and a great advantage would result to the city from the giving of employment to the trades connected with building. The poverty of the city was to a great extent owing to want of employment, and it was impossible not to feel that the restrictions imposed by trades' regulations contributed not a little to the difficulty of obtaining employment.

DISLOCATION OF PHALANGES BY A BLOW FROM A CRICKET-BALL.

To the Editors of THE LANCET.

SIRS,—This accident, which came under my observation lately in the cricket field, presents an interesting feature in its mode of causation. It occurred to the wicket-keeper, who wore the usual gloves, and was caused by a blow on the tip of the middle finger of the right hand. As a result there followed a complete dislocation of the second phalanx forwards on the first. It was easily reduced by forcible extension.

I am, Sirs, yours faithfully,

Coventry, Oct. 15th, 1898. RICHARDSON RICE, M.D. Dub.

*** It is not rare for a finger to be dislocated by a cricket-ball, though it is commonly displaced *backwards*. It is rare for the phalanx to be dislocated forwards.—ED. L.

DELIVERY OF THE AFTER-COMING HEAD IN CONTRACTION OF THE PELVIS.

IN the *Deutsche Medicinische Wochenschrift* of Oct. 20th Dr. Radojewski of Janowitz records 3 cases in which he extracted the after-coming head by breaking up the brain through the vertebral canal and washing away the brain substance with a current of water. In his first case, which occurred about twenty years ago, the midwife told him on his arrival that it had been a foot presentation and that she had pulled away the body from the head. He had not brought a cranioclast with him and after vainly endeavouring to extract the head with a hook he passed a uterine sound into the skull through the spinal foramen, broke up the brain, passed an elastic catheter into the skull, attached it to an enema syringe, and injected water till the brain was washed away, after which the head was easily removed with the hook. His next case was in October, 1897, when he was called to a primipara whose conjugata vera scarcely exceeded five centimetres (two inches). The presentation being transverse he turned, but the head could not be extracted by moderate traction and external pressure, and as the child was dead he divided the spinal column between the second and third dorsal vertebræ, broke up the brain partly with a catheter and partly with a wire introduced through the spinal foramen, and washed away the brain with water, after which the head was easily withdrawn. In the third case the operative part was quite similar to that in the second, except that it was impeded by the midwife having previously fractured the cervical vertebræ. As a result of this experience Dr. Radojewski has devised an instrument which is made by Messrs. Evens and Pistor of Cassel. It is called the "cerebrotome aspirator," and consists of a tube a foot long containing a spring 3½ in. long which projects more or less beyond the tube as may be required. The spring is used to break up the brain and is then withdrawn from the tube to which a syringe half full of water is attached and the brain substance is removed by alternate injection and aspiration of the water.

"AN APPEAL ON BEHALF OF THE WIDOW OF THE LATE JAMES McGREGOR LAING."

To the Editors of THE LANCET.

SIRS,—The following subscriptions have been received in addition to those already acknowledged in THE LANCET of July 9th:—

	£	s.	d.		£	s.	d.
Dr. Herbert L. Spencer ...	2	2	0	Mr. J. P. Gannon, Board of Trade	2	2	0
A Poor Medico, Edinburgh	0	5	0	Dr. J. Power, Nailsworth	1	1	0
Professor Findlay, Aberdeen	1	1	0	Dr. George Hunter, Edinburgh	1	1	0
A Mite	0	5	0	Dr. Duka	1	1	0
Mr. Edward Bartlett ...	1	1	0	Mr. T. Corbett, Droitwich	1	0	0
Dr. E. P. Scott, Brussels...	1	0	0	Dr. G. F. Grant, Motihari, India...	1	0	0
Postal Order, Maxwell ...	0	2	6				
Mr. Edmund Owen ...	2	2	0				

We wish to say that, in spite of many attempts to find an established business or a suitable place to begin a shop, we have hitherto not been successful and we have, in consequence, been obliged to give Mrs. Laing, to enable her to live, some £15 out of the money so kindly subscribed. Any further sums will be gratefully acknowledged. Mrs. Laing's youngest boy, John Bertram Laing, now ten years old, will make his third application in May next to be put upon the foundation of Epsom College. Help in this direction will be greatly esteemed.

We are, Sirs, yours faithfully,

J. PICKETT, M.D. St. And. (26, Colville-square, W.),
REGINALD HARTLEY, M.D. Durh. (68, Porchester-terrace, W.)

Oct. 24th, 1898.

DANGERS IN MILK IN MANCHESTER.

APROPOS of the recent investigations by Professor Delépine and Dr. Niven as to the dangers from the milk brought into Manchester the Corporation are seeking powers similar to those contained in the Glasgow Police Amendment Act in connexion with the sale of milk from diseased cows, &c. The City Council decided also to give their support to the Camberwell Vestry in getting a Bill introduced into Parliament for dealing with the mischief arising from condensed milk.

"THE POSITION OF THE ASSISTANT WITH REGARD TO FEES EARNED AT CORONERS' INQUESTS."

WE regret to find that by a slip we have said the exact contrary of our meaning in a note last week in answer to a question from a correspondent on this subject. By the context it is clear that we designed to say that these fees belong legally to the principal—as, of course, they do—but we have written that they "belong to A," and "A" was the letter used by our correspondent to designate the assistant.

"THE CLIMATE OF THE DISTRICT AROUND JOHANNESBURG."

To the Editors of THE LANCET.

SIRS,—Dr. E. Symes Thompson has been kind enough to draw my attention to an inquiry inserted in THE LANCET of Oct. 22nd by a correspondent who desired information about the suitability of the neighbourhood of Johannesburg for phthisical patients and who is anxious to avoid dust-storms. It must be understood that almost all colonial towns are extremely dusty at certain seasons, as the corporations cannot afford the expense of preventing this in dry climates. In the vicinity of Johannesburg the immense traffic and the mining operations create much dust, which is driven about by the high winds. Moreover, the grass there is not so thick as it is, for instance, along the Drakensberg in the Orange Free State. If it is merely a question of ascertaining which part of the elevate region of South Africa is best suited for phthisical patients I

Digitized by Google

should recommend the locality of Harrismith on the Natal border, in the Orange Free State. The altitudes of Johannesburg and Harrismith do not differ very much, but the latter place has a decidedly purer and more bracing atmosphere. Speaking generally, the districts along the Drakensberg range on the western side are not so dry as the country west of them, but this fact is of little consequence. My personal observations have persuaded me that very frequently too much stress is laid on the extreme dryness of a climate in combination with high temperature. The exceptional power displayed by the atmospheric conditions of the elevated region of South Africa in restoring phthisical patients to health is principally due to two factors: (1) height above the sea level, which improves the quality of the blood and gives increased vital energy; and (2) the warm, dry atmosphere, which permits the air indoors to be continually renewed. It is scarcely necessary to close bedroom windows either by day or by night, the good result being, of course, due to the continual fresh air and not to its mere warmth and dryness. A further requisite is that the atmosphere must be bracing, for if the locality is very hot in summer the vital energy is reduced; many patients lose flesh and do not easily make it up in winter. Phthisical patients in England will be glad to hear that a movement is now on foot to establish a large and well-appointed sanatorium in the Harrismith district. In my opinion, knowing the greater part of South Africa as I do, that place is the most suitable and has the most effective climate for the purpose in question.

I am, Sirs, yours faithfully,

London, Oct. 24th, 1898. HENRI, COMTE DE MARILLAC.

*** We publish the Comte de Marillac's letter, though it s from a lay pen, as it records personal experience.—ED. L.

QUACKERY AT THE CAPE AND ITS PUNISHMENT.

FREEDOM as understood over here and at the Cape differs widely. Here any ignoramus can treat patients and receive money for so doing without let or hindrance. The treatment may be something tangible, as in the case of massage houses, or it may mean nothing at all, as in the case of the "Christian Scientists." Now in democratic South Africa they will not stand this sort of thing. Only recently a labourer was charged with practising as a medical practitioner without having a licence as required by law. A gentleman who suffered from internal pains was treated by the defendant, who gave him a medicine composed of herbs and he soon got better. Witness's father gave defendant a heifer as a fee. Another patient said that defendant had treated him but he got no better. He had promised to give a heifer but as he got no better he did not pay. Eventually defendant was fined £5.

THE FOUR SQUARE HUMOURS.

To the Editors of THE LANCET.

SIRS,—For some weeks I have been endeavouring to find the meaning of a certain phrase. Your valuable little contemporary *Notes and Queries* has hitherto been unable to suggest a solution, and I venture therefore, the rather as the phrase in question has a more or less medical air, to appeal to the readers of THE LANCET. It occurs in a legend scratched, with a diamond apparently, on a small window-pane once in use in a very old Shropshire house, and still carefully preserved. I need not trouble you with the whole of it, but I may say that it concludes with the words: "Whom God long preserved in the promisses and from the four square humors." It is as to the significance of the last three words that I seek information. The "four humours" of the classical physicians one is, of course, familiar with, but how could a man speak of being "preserved" from all four? He must, one would think, have had at any rate one. And why square? The date, 1690, is likewise inscribed on the pane. Can the "four square humors" by any chance have been a medical colloquialism or provincialism two centuries ago? I can find no trace in any dictionary. It has struck me that some medical man living in the Midlands may possibly have heard of the phrase as once current, and if he has I shall be grateful if he will say so, and at the same time hazard a solution.

I am, Sirs, yours faithfully,

United University Club, Oct. 26th, 1898. ARTHUR GAYE.

THE USE OF THE CRUET IN FIRST AID.

A CORRERPONDENT asks us for the title of a book by one of the staff of St. Mary's Hospital containing directions for the use of the cruet in first aid. Can any of our readers supply the information?

"BARKOO ROT."

To the Editors of THE LANCET.

SIRS,—I have just noticed in THE LANCET of Oct. 8th an inquiry as to the nature of Barkoo rot it should be Barcoo rot, named from the Barcoo district in Queensland, where it is very prevalent), and as I spent three years in that district and saw a great deal of it I beg to submit the following information. I saw it among all classes of men who do rough work in the bush. It is chiefly seen on the hands, as these are especially exposed to injury. The slightest abrasion of the skin may start it. The essential feature is that these abrasions show no disposition to heal for some reason. They suppurate, involving areas much larger than the original focus, and this condition may last for weeks and months. Out there it is looked upon as having a constitutional origin and the antidote which I have seen adopted and do good is tinctura ferri perchloridi taken internally—an empirical remedy; but its effects justify its use. It does not seem to be especially prevalent among men following any special occupation or using special implements, and I can offer no theory as to its pathology. It reminds one of an obstinate coccl infection, but local applications seem to have no effect on it. To put it popularly, the hands seem to get sodden with the constant sweating and the skin becomes so devitalised that the slightest injury causes an abrasion and starts the unhealthy process of ulceration and suppuration.

I am, Sirs, yours faithfully,

EUSTACE BARTON, M.R.C.S. Eng.

Cromwell-road, S.W., Oct. 22nd, 1898.

CURRY FROM A FRENCH POINT OF VIEW.

WE learn from a French journal devoted to hygiene that *le karik* is a very popular condiment in Hindustan and that it has made its way throughout the entire Orient. The natives of these regions value it highly as a powerful aperitive, and also employ it freely in the treatment of a multitude of maladies inclusive of anorexia, atony of the digestive tract, gastric and intestinal dyspepsia, muscular weakness, organic wasting, and climatic debility. When well prepared *karik* stimulates the appetite to a wonderful extent. It consists of morsels of chicken ("the muscular parts" be it noted, not the bones or feathers), together with a *sauce piquante* composed of pepper, ginger, canella, cachumba, and sundry other plants having aromatic qualities, the whole being spread abundantly over very white rice and served up piping hot.

Enquirer.—The condition is an exceedingly common one and its symptoms are always attributed by the victims to impossible telepathic influences. It is not "a clear case of insanity," but the sufferer has lost his mental balance, as his medical man has indicated to him, and we advise him to place himself under proper directions.

A Constant Reader is recommended to apply to Mr. Walter Reeve, 38, Manchester-street, W., who will be able to give him the information he requires. We have not attempted to give a list of the books particularly required for any examination.

Manor Park.—The address of the Irish Medical Schools' and Graduates Association is 11, Chandos-street, W., and that of the honorary secretary, whose name is Mr. James Stewart, F.R.C.P. Edin., is Dunmurry, Sneyd-park, Clifton, Gloucestershire.

Plague.—We are not aware that the Government require further assistance, but application should be made to the India Office and the Colonial Office.

Books.—The best pamphlet on the subject is the well-known one by Dr. J. C. McVail entitled "Vaccination Vindicated."

Mr. E. H. Snell.—We have made the correction. The fees, of course, belong legally to the principal.

M.B., R.N. has omitted to give his name and address.

Disgusted.— he matter will r iv our attention.

SCHACHT'S
PEPSINE WITH BISMUTH

(PEPSINA LIQUIDA cum BISMUTHO, SCHACHT).

A bright, palatable fluid of the highest activity and purity, that will preserve its characters when kept any length of time, without acquiring colour, smell, or deposit.

Each drachm contains, in a concentrated form, besides the fluid Pepsine, a full dose of Schacht's Liquor Bismuthi. Invaluable in Gastric Irritation, Pyrosis, &c.

DOSE: One Drachm, diluted.

N.B.—Peps. Liq. c. Bismuthi Co. contains, in addition, 1 gr. of Soluble Euonymin in each drachm.

In 4-oz., ½-lb., and 1-lb. Bottles.

THE "SCHACHT" TRADE MARK GUARANTEES EXCELLENCE.

THE "SCHACHT" TRADE MARK GUARANTEES EXCELLENCE.

PEPSINE WITH DIASTASE

(THE "SCHACHT" BI-DIGESTIVE).

A bland liquid of very agreeable flavour, presenting both ferments in fullest activity. Although such a combination, capable of converting both albuminoid and starchy foods, is often needed by physicians as a dietetic aid in disease or in convalescence, nothing of real value has hitherto been available. A most active, palatable, and reliable preparation is now offered to the profession and will surely be appreciated.

DOSE: From a dessertspoonful to a tablespoonful with each meal.

In 8-oz. and 16-oz. Bottles.

GILES, SCHACHT & CO., Clifton, Bristol.

"APENTA"

THE BEST NATURAL APERIENT WATER.

APENTA WATER IN THE TREATMENT OF OBESITY.

"The *Berliner Klinische Wochenschrift* for March 22nd, 1897, speaking of some experiments made under Professor Gerhardt's direction in the Charité Hospital as to the value of APENTA water in the treatment of obesity, says that such experiments could not be carried out until quite recently, on account of the inconstant composition of the bitter waters coming into the market. In this respect, the APENTA water is favourably circumstanced, and it was chosen for these observations because of its constancy of composition. The conclusions arrived at as to the value of APENTA in the treatment of obesity, and as to its influence on tissue-change without causing any nutrient losses, were that it succeeded in producing a reduction of fat in the body without detriment to the existing albumen, and that the general health of the patient suffered in no wise, and the cure ran its course in a satisfactory manner."

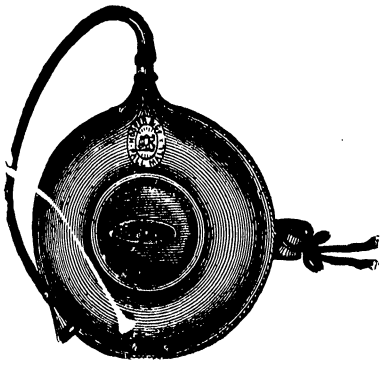
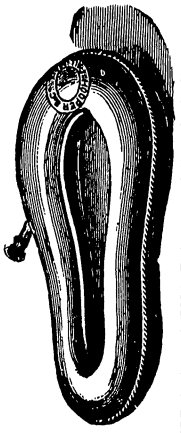
HOOPER'S ELASTIC WATER OR AIR BEDS AND CUSHIONS.

To be used on any ordinary Bedstead or Couch.

For Paralysis, Fevers, Consumption, Rheumatic Affections.

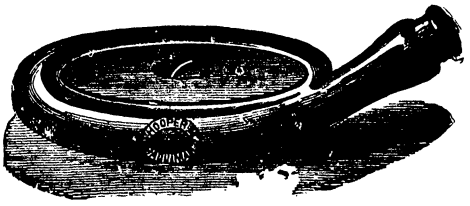


For Sale or on Hire.



For Bedsores, Spinal Affections, and all Bedridden Patients.

HIGHEST AWARD AT THE INTERNATIONAL MEDICAL AND SANITARY EXHIBITION, 1881.

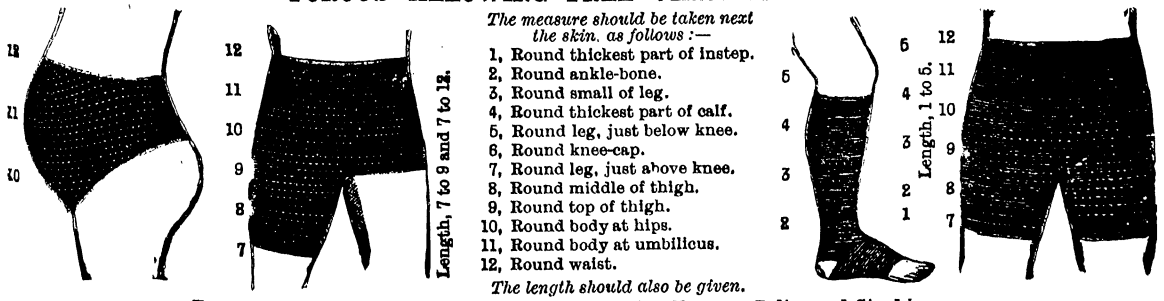


☞ Messrs. Hooper & Compy. beg to invite the attention of the Profession to their system of hiring their Water Beds otherwise than in contagious or infectious diseases, and feel assured that where outlay is a consideration the Profession will appreciate and avail themselves of this hiring system.

ELASTIC INFLATING BED PAN.

ELASTIC INFLATING BED SLIPPER.

SANITARY BED PAN.



IN WHITE PORCELAIN OR GUTTA PERCHA.

Fitted with lid and stopper to prevent effluvia when removed from the Patient.

The Elastic Bed Slipper and Bed Pan, from their softness and elasticity, are peculiarly adapted to Ladies after confinement, and to Invalids who, from emaciation or other causes, cannot bear the hardness of ordinary utensils.

HOOPER'S SPIRAL ELASTIC BANDAGES.

POROUS—ALLOWING FREE VENTILATION.

The measure should be taken next the skin, as follows:—

1, Round thickest part of instep.
2, Round ankle-bone.
3, Round small of leg.
4, Round thickest part of calf.
5, Round leg, just below knee.
6, Round knee-cap.
7, Round leg, just above knee.
8, Round middle of thigh.
9, Round top of thigh.
10, Round body at hips.
11, Round body at umbilicus.
12, Round waist.

The length should also be given.

Experienced Male always in attendance for fitting Trusses, Belts, and Stockings.

JOSEPH TURNER & CO.'S
NEW SYNTHETIC REMEDIES.

SYNTHESIZED and MANUFACTURED in ENGLAND.

PIPERIDINE TARTRATE. The New Uric Acid Solvent.

Piperidine possesses uric acid solvent powers greatly superior to any other known substance, and, in combination with tartaric acid forms a pleasant salt, which may be taken in 5 to 15 gr. doses in all wines, mineral waters, &c., at or before meals.

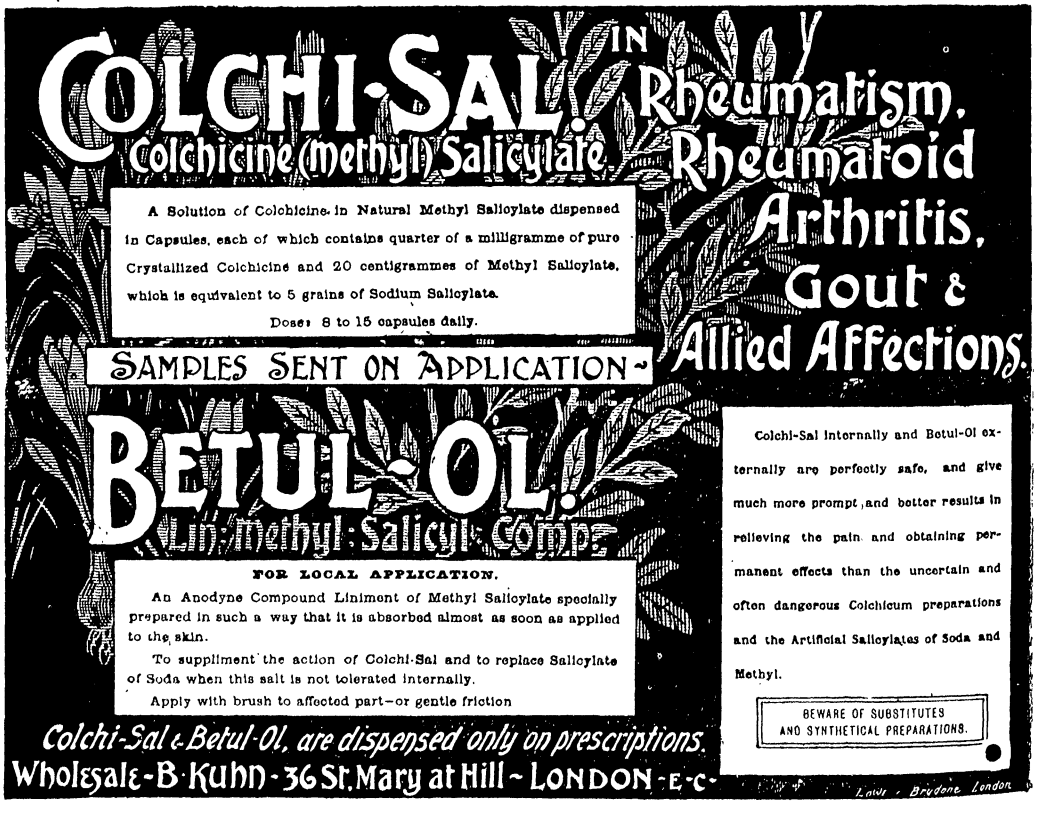
(See THE LANCET, July 23th, 1898; BRITISH MEDICAL JOURNAL, Feb. 27th, 1897; CENTRALBLATT DER PHYSIOLOGIE, Bd. iii., p. 434.)

GUAIPEROL (Guaiacolate of Piperidine).

This **REMEDY for PHTHISIS**, which combines the antiseptic properties of Guaiacol with the vascular tonic action o Piperidine, has been tried with considerable success at the London and other Chest Hospitals. It has not the irritant properties o Guaiacol, and possesses many advantages over the latter substance and preparations of the same now on the market. DOSE: from 10 gr twice a day, preferably in cachets, after meals.

(See BRITISH MEDICAL JOURNAL, January 16th, 1897, and July 16th, 1898, &c.)

ERYTHROL TETRA NITRATE (Turner).



The New Vaso Dilator.

The difference between the action of Erythrol Tetra Nitrate and other vaso dilators consists mainly in the fact that the vaso dilatatio produced from it is of a *much more permanent* nature, the administration of gr. i. by the mouth causing a reduction in arterial tensio lasting for more than five hours.

(See BRADSHAW LECTURE, 1895; CROONIAN LECTURE, 1896; BRITISH MEDICAL JOURNAL, April 10th, 1897, January 1st, 1898, and January 8th, 1898, &c.)

SOLE PATENTEES & MANUFACTURERS, from whom Samples and Literature may be obtained:—

An Address
ON
ELEMENTS OF PROGNOSIS AND PRINCIPLES OF TREATMENT IN CARDIAC DISEASE.

Being the Introduction to a Discussion at the Medico-Chirurgical Society of Norwich, delivered on Nov. 1st 1898,

BY G. A. GIBSON, M.D., D.SC. EDIN.,

SENIOR ASSISTANT PHYSICIAN TO THE ROYAL INFIRMARY, EDINBURGH; LECTURER ON MEDICINE AND CLINICAL MEDICINE IN THE MEDICAL SCHOOL, EDINBURGH.

MR. PRESIDENT AND GENTLEMEN,—My first duty is to attempt in some measure to express my sense of the honour you have conferred upon me by requesting me to open this discussion. When your honorary secretary communicated your flattering invitation my first feeling was that of weighty responsibility, such as might assuredly arise in the mind of anyone under the circumstances. The corner of England in which we are met is hallowed by the presence of ancient and honourable memories. When the dawn of history first pierced the gloom in which our land was shrouded and threw its light upon this portion of the island it was the scene of tragic events attendant upon the glorious struggle for freedom made by a brave race under the leadership of an heroic queen. Since then this classic region has been the stage upon which has been played many an act in our country's stirring drama; it has been the arena of numberless victories in peace no less than war. The art of healing has, amongst pacific successes, achieved here numerous triumphs. It owes much in almost every one of its branches to those who have lived and laboured, nay, who live and labour, within sight of these walls. For obvious reasons a certain amount of reticence must be observed, but you will perhaps allow me to refer to the deep debt of gratitude to those distinguished men under which medicine, as well as surgery, labours, and to give utterance to the feeling of thankfulness that they are still amongst us to aid us by their counsels and shed lustre upon our vocation. Another reason for the sense of diffidence which threatened to overcome me lies in the fact that your society has from time to time been graced by the presence of men bearing names of world-wide renown, who have at your request brought before you the results of fruitful years devoted to the pursuit of knowledge. Acquaintance with this circumstance only served to deepen my apprehension lest any oblation it might be in my power to offer should be all unworthy of the occasion. Yet in spite of these weighty considerations the invitation vouchsafed by your secretary was so cordial in its tone, so instinct with that spirit of comradeship which has contributed so much to the solidarity of our profession, that it seemed my bounden duty to cast aside my scruples and respond to your summons as the most suitable manner of acknowledging your kindness.

The subject which you have requested me to bring before you to-night is one of such wide import, and at the same time so full of vexed questions, as to be of more than ordinary difficulty. It is, moreover, possible that it may be regarded as almost, if not quite, worn threadbare; it is, in truth, a theme often discoursed upon, yet with the onward progress of knowledge it is one that allows reconsideration from time to time. The views we hold must of necessity alter with the advent of new facts from nature. As Goethe says:[1]

> "Grau, theurer Freund, ist alle Theorie,
> Und grün des Lebens goldner Baum."

The title which has been adopted involves the consideration of what is really but one subject regarded from two different points of view. It is, in truth, absolutely impossible to sever prognosis from treatment. The close association between the gift of foreseeing events and the ability to modify their course is well recognised even amongst those who have but little direct connexion with the art of healing. Many of you will, no doubt, remember the pathetic lament put in the mouth of the good Dr. Chassaigne by one of the greatest writers of the age[2]: "Moi qu'on imagine si savant, si armé contre la mort, je n'y ai rien compris, je n'ai rien pu, pas même prolonger d'une heure la vie de ma fille. Et ma femme, que j'ai trouvée froide dans son lit, lorsqu'elle s'était couchée la veille mieux portante et si gaie, est-ce que j'ai été capable seulement de prévoir ce qu'il aurait fallu faire? ..... Non, non!" Here we have from the pen of one of the closest observers of men and things the clearest recognition of the interdependence of foresight and action. It is perfectly true that a contrary opinion has at times been urged. One of the greatest teachers of modern times has, for instance, stated[3] that "the *prognosis* (or foreknowledge) of the course and event of disease has but little connexion with the promotion of the art of healing." This is assuredly a hard saying to have fallen from the lips of the eloquent Watson in those lectures which are still the object of our admiration. In early ages, and amongst robust peoples, the mind of man has ever sought with hungry longing to peer into the gloom enshrouding the future. It has been somewhat otherwise when a later phase of progress has been reached; at such a stage there has often been no yearning to raise the veil hiding coming events. The Augustan poet deftly handles this shrinking in many a lyric gem, but nowhere perhaps does he more gracefully touch the subject than when he sings:—[4]

> "Prudens futuri temporis exitum
> Caliginosa nocte premit Deus,
> Ridetque, si mortalis ultra
> Fas trepidat."

It is assuredly somewhat less than scientific to recoil before the problems which are connected with the future or to belittle the influence upon action which foreknowledge must exert. If it be true of any branch of knowledge, it is most certainly true of medicine, as Carlyle says,[5] that "the Present holds in it both the whole Past and the whole Future"; "the Future," also, as the same great writer remarks in another place,[6] "is not dissevered from the Past, but based continually on it." It is scarcely possible to imagine anyone who does not attempt to solve at once problems connected with the origin and the result of disease, for, as Hume puts it,[7] "determined by custom to transfer the past to the future in all our inferences," we cannot avoid projecting the results of previous experience into the consideration of coming possibilities. To one who has been trained, as all of us have been, to observe the sequence and event of disease, its probable terminations may, in most instances, be with considerable certainty predicted. "To foreshow these," as your great fellow-townsman, Sir Thomas Browne, remarks in regard to another subject,[8] "is not prophecy but prognostication." It is therefore incumbent upon the physician to remember the adage of the old playwright:[9]

> "Istuc est sapere, non quod ante pedes modo'st
> Videre: sed etiam illa, quæ futura sunt,
> Prospicere."

An engrossing attention to the conditions and circumstances of the moment is not enough. The "mens provida rerum futurarum" of the Roman orator [10] is of a value in medicine, as in other walks of life, that cannot be over-estimated. No doubt the "aliquid in animis præsagiens atque divinum,"[11] of the same author is an inherent faculty, yet it is one that can be successfully cultivated. It is the duty of everyone who professes the art of healing to extend it, for "he will manage the case best," as the Father of Medicine puts it,[12] "who has foreseen what is to happen from the present state of matters." While it is necessary for the purpose of systematic discussion to consider prognosis and treatment separately, it must ever be borne in mind that the two go hand in hand—that, in truth, to be forewarned is to be forearmed.

The elements of prognosis as regards heart disease have in recent times received much attention. The observations of Clark,[13] Pye-Smith,[14] and Broadbent[15] have brought, as it

were, to a focus many of the views of modern time, while Duckworth in his interesting lectures has also dealt with the subject. The last-mentioned author writes as follows:[16] "The principles on which a prognosis is framed in respect of valvular disease are now well understood. All depends on the constitutional powers, habits, and environment as regards the integrity and nutrition of the cardiac muscular fibres." There is no doubt a large element of truth in these remarks, but it is by no means easy, as will be shown shortly, to arrive at the precise conception which he speaks of with reference to the muscular wall of the heart. If we proceed analytically to consider the various factors upon which a forecast of the future must rest we shall find that there are certain agencies which may all be classed as *general* and other influences to be termed *special*. Let us, in the first place, consider the former.

Firmly believing, as most of us do, in the great doctrine of inheritance we shall find in the past history of the family determining influences which, acting upon the germ plasm, provide for greater or less resistance to the forces of dissolution. That cardiac lesions are hereditary has long been known and our conceptions have been rendered clearer by the work of Leube[17] and Pierson.[18] A glance, therefore, at the family history will in every instance be of great value in framing the prognosis. The past events of individual life without doubt exercise vast influence over the course and event of disease. Previous illness, over-exertion, excess,—all these factors are potent for evil. The great oriental doctrine of Karma, is singularly applicable to the effects of former actions upon the individual. The age and sex of the patient must be taken into account. Affections which begin in tender years are much more serious in their results than those which occur after the organism has attained a riper growth. The influence of sex, moreover, is of far-reaching importance in heart affections. It is universally known, for example, that aortic affections are more particularly found in men, while mitral lesions obtain principally among women. It is quite as generally recognised that the mode of life and the events incidental to either sex are influential as regards the course of a cardiac lesion. The occupation and surroundings need not detain us; their influence for good or ill is so far-reaching as to require but little comment. These general considerations may be summed up by stating that when, from the facts of family tendency or personal history, individual conditions or special environment, the organism is so conditioned as to be in the possession of healthy structures and the performance of healthy functions the prognosis will be by so much the better than if structure and function tend to be rendered faulty by any departure from favourable conditions.

The special factors in reaching a definite prognosis are manifold, but confining ourselves to cardiac lesions and excluding affections of the peripheral circulation we shall be able to arrange them into groups. In lesions of the pericardium interference with the circulation ensues from one or more of three agencies. The presence of an acute process may, by extension to the myocardium, produce a paralytic myocarditis and in this way diminish the cardiac energy. It is fortunately averted by the presence of the fibrinous deposit which, as was pointed out by the eloquent Hilton[19] in his classical lectures on "Rest and Pain," acts as a protection. There may also be the presence of adhesions, as shown by Morgagni,[20] Kennedy,[21] and Wilks,[22] which interfere with the free movement of the cardiac muscle. There is, further, the presence of an excessive amount of serous secretion which, as clearly grasped more than two centuries ago by the great Lower[23] and physiologically explained by Cohnheim[24] and Starling,[25] interferes with diastolic aspiration. Physical examination will in almost every instance reveal with tolerable certainty the cause of the interference. The feebleness of the sounds and the waning yet frequent pulse suffice to diagnose myocarditis arising by extension. The indrawing of the interspaces around the apex beat and the diastolic rebound will give a diagnosis of adhesions, while the distant character of the cardiac sounds and the characteristic enlargement of the dulness on percussion ought to prove that an excessive accumulation of serum is present in the sac.

Endocardial lesions may be, as in the case of most other diseases, acute or chronic. Modern pathological research has shown us that all forms of acute endocardial lesions are due to, or associated with, the presence of micro-organisms, but, whether from differences in the virulence of these infective agents or from the varying powers of resistance possessed by the tissues, the effects of these lesions are very diverse, and it at present seems extremely difficult to foresee the probable termination in any acute endocarditis. Many a case which in an early phase appeared full of hope suddenly and unexpectedly undergoes an unfavourable change and proceeds to a fatal termination, while the converse, although not so frequently encountered, also occurs.

When we turn to the chronic affections of the orifices and their cusps we find, on the whole, a general consensus of opinion as regards the relative dangers attendant upon lesions of the different valves. This agreement, however, is subject to a few individual variations. Speaking generally, it may safely be assumed that aortic incompetence is the most dangerous, and aortic obstruction the least serious, of valvular affections, while mitral lesions occupy an intermediate position, mitral obstruction being rather more formidable than mitral incompetence. The reason for the different degrees of danger presented by these lesions may be summed up by stating that whereas aortic incompetence gives rise to considerable oscillations of pressure, and is at the same time apt to be attended by coronary lesions, mitral affections lead to symptoms of backward pressure upon the lungs, and secondly upon the right side of the heart and the systemic veins. We know from the work of Cohnheim[26] and Rosenbach[27] that artificial valvular lesions do not in themselves cause any loss of mean blood-pressure or disturbance of the equilibrium of the circulation, and it can only, therefore, be as the result of continued interference with the mechanism of the heart and prolonged call upon its reserve of energy that valvular lesions produce their evil effects. The results produced by those lesions are almost entirely dependent upon the state of the cardiac muscle and they must be considered in dealing with the next factor.

The condition of the muscular wall of the heart is the predominant factor in prognosis. Whether arising primarily in itself or secondarily as the result of pericardial or endocardial lesions, any disturbance of normal conditions in the myocardium brings about an alteration of the relative blood-pressure in different parts of the circulation. The nutrition of the heart muscle depends in the first place upon an adequate supply of healthy blood. The maintenance of normal structure in the heart involves the integrity of every bodily function, but, above all, the performance of digestive and metabolic processes in such a satisfactory manner as to produce blood of adequate quality. This must, in the next place, be supplied to the heart in sufficient quantity. Two great points are to be considered here. The coronary arteries, whose relation to the heart was first shown by Morgagni in his earliest work,[28] may be of a calibre too small for the supply of sufficient blood to the heart muscle. This undeniably takes place in sclerotic and atheromatous changes. It is scarcely necessary to refer to the frequent association of coronarteritis and interstitial myocarditis, or so-called fibroid degeneration. On the other hand, when the general blood pressure in the arterial system is too low, and when there is a tendency to venous remora, the heart is apt to participate in the general stagnation, and it undergoes the chronic fibroid degeneration first described in this connexion by Jenner.[29] The cardiac muscle may therefore suffer primarily or secondarily.

The practical question now arises, if the whole prognosis and treatment of cardiac affections depend upon the condition of the cardiac muscle, how is this to be gauged? Do our methods of physical examination furnish us with results of sufficient accuracy to give the means of reliable forecast and adequate management? The investigation of the pulse

reveals, without doubt, most important facts as regards arterial pressure, yet it is by no means easy to determine the extent to which the different factors involved in the maintenance of the pressure are respectively engaged. It is unnecessary to mention that no instrument yet devised for recording the movements of the pulse is of the least importance from the point of view of prognosis. No form of sphygmograph is of the slightest assistance, and the educated finger can alone be depended upon in attempting to foretell the probable course of events. It is otherwise with regard to certain of the modern instruments intended to measure the arterial pressure. The sphygmomanometer of von Basch[30] and the sphygmodynamometer of Oliver[31] are both of importance in this respect. My own observations with these instruments have been scanty, but for some time the sphygmometer of Hill and Barnard[32] has been in constant use in my wards. The general results obtained by means of it show that in healthy young men the pressure has usually been equal to from 105 to 135 mm. Hg., while in failing compensation it may be as low as 50 or 60 mm. Hg. It is by no means certain that these figures give any real information as regards the energy of the cardiac muscle. There may, for example, be a high arterial pressure, notwithstanding a feeble heart, simply because the peripheral resistance is excessive.

The energy of the systole and the intensity of the cardiac sounds or murmurs must of necessity be taken into account. These are subject to fluctuations according to the condition of the parietes, and this consideration will necessarily lead to the employment of great care in attempting an estimation of them. The cardiograph is for the purpose now under discussion of even less utility than the sphygmograph. Many attempts have been made to estimate the cardiac energy by the investigation of the heart sounds by means of the microphone. This is a subject which for some time engaged my earnest attention, but thus far no results of the slightest value have been attained. Recently it occurred to me to inquire whether the electro-motive force generated by the heart might furnish any prognostic indications. We know from the investigations of Engelmann,[33] Marchand,[34] Burdon Sanderson and Page,[35] and more recently of Waller,[36] that the movements of the heart are accompanied by electric variations which are easy to demonstrate. An electrode made of zinc, covered by chamois leather and moistened with brine, is applied to the front of the chest near the apex of the heart; one or two fingers of the right hand are placed in a vessel containing salt solution and the electrode and brine are connected with a capillary electrometer. The mercury in the electrometer is seen to move with a sudden throb immediately before each beat of the heart, the time interval usually being about 0·015″. When observed with a high power of the microscope in order to ascertain the extent of this electric variation it occurred to me that a micrometer might be employed, and by its means it has been possible to determine that there are considerable variations in the amount of electro-motive changes. The extent of the movements in the electrometer may be recorded by photography, as has been so beautifully done in Waller's experiments, or the movements may be shown graphically by the use of the projection microscope. There are certain difficulties in regard to this subject. In the first place, it cannot be assumed as absolutely certain that the electro-motive changes bear any constant relation to the amount of muscular force; and, in the next place, it will be readily granted that there are without doubt large possibilities of error in consequence of differences in conduction. My investigations upon this subject are as yet only in their infancy, but it seems to me that it is of sufficient interest to bring before you to-night. Although there are but few definite facts to submit for your consideration it may be stated that while in certain individuals with a feeble circulation the variation observed by the micrometer does not exceed one micro-millimetre, in others the extent of movement rises to as much as three.

The size of the heart is a factor of some importance. If it be found by palpation and percussion to be considerably enlarged, although feeble, thereby showing a condition in which dilatation is the principal state, it necessarily leads to apprehensive conclusions. If, on the other hand, it is enlarged but acting powerfully, pointing to the presence of hypertrophy, it again aids the observer by warranting a more hopeful forecast of the future. In this place it may be well to venture upon a note of warning. During the last few years great stress has been placed upon the results of percussion, and enormous changes in the size of the organ have been demonstrated both by percussion and by the employment of radiography. Such statements have been shown by Poore[37] on mathematical grounds to rest on conceptions which can scarcely satisfy the reason of anyone trained in the methods of philosophic doubt. These changes appear, as is urged by A. Morison,[38] to be more the result of apparent diminution in consequence of altered position and of modified form than of real alteration in size.

The condition of the heart muscle can, according to our present lights and our present methods, only be estimated with any approach to exactness by comparing the results of the investigation of the pulse and the examination of the heart. In addition to the results obtained by physical examination of the chest we find in many other symptoms evidence of considerable value. The entire range of effects produced by backward pressure—the enlargement of internal organs, the catarrh of mucous membranes, the dropsy of serous membranes, and the anasarca of subcutaneous tissues—throw, as is so well known, a lurid light upon the condition of the patient. It is far from my present purpose to inflict upon you any analysis of the symptoms produced by such pathological processes; suffice it to say that the modified functions of the structures so affected, familiar as they are to everyone, are of at least as much value as the facts obtained by a rigid investigation of the chest.

To sum the entire subject of prognosis up it may be said that when the arterial pressure is good, the heart not unduly hypertrophied, and the system at large free from any appearance of disturbed equilibrium, the prognosis may be regarded as satisfactory; when the converse conditions are present it must be framed with greater reserve.

It is time to turn now to the second part of our subject—the principles of treatment. It may be premised that they are few in number. The most important object which must be kept in view is the maintenance of the blood-pressure at an adequate height; this aim involves the elevation of arterial, the diminution of venous, pressure. These effects must be produced by acting upon the heart on the one hand and upon the arterioles on the other. The condition of the blood as regards its nutrition will require attention, but in cardiac failure it is a matter of obvious difficulty to arrive at correct conclusions on this subject. As is now well known, in the most profound cyanosis the number of red blood corpuscles is enormously increased; the white blood corpuscles are also somewhat more numerous and the hæmoglobin is large in amount. Speaking generally, it may be said that 8,000,000 red blood corpuscles, 15,000 white blood corpuscles, and 120 per cent. of hæmoglobin come not infrequently under observation. That these changes are compensatory and are produced by the long life of the individual corpuscles through diminished wear and tear has been urged by myself.[39] It is, however, quite possible that they are simply caused by backward pressure as the result of stagnation. This nevertheless does not commend itself to my judgment. An easy way of solving the question would be by the comparison of arterial and venous blood if it were in any cyanotic case justifiable to perform arteriotomy. These facts are submitted to you with the view of showing how difficult it is to come to any direct conclusion with regard to the condition of the blood in respect of nutrition. By acting upon the secretory and excretory mechanism the blood may be rendered more pure, while the relative arterial and venous pressures may also tend to be approximated to the normal. It need scarcely be added that by stimulating the nervous mechanism, and in this way liberating nerve energy, very considerable benefit will accrue to the patient, through the influence which is indirectly exerted on the entire system.

In the practical application of therapeutic principles to the treatment of cardiac disease it is necessary, in the first place, to consider some general methods. Nowhere is the wholesome influence exerted by air and light better seen

than in the management of circulatory disturbances. Good ventilation and such an exposure as will secure as much sunlight as may be obtained in our country must therefore be provided. In many cases it will be necessary to seek a more genial climate for the winter and spring months than our own country affords. In serious conditions the inhalation of oxygen may be of vital importance. Sufficient sleep, alternating with some gentle intellectual exercise, must in every case be ensured. The former is frequently aided, even in the gravest cases, by the use of two beds for the patient, one to be employed during the night, the other during the day. As regards mental operations, it need hardly be remarked that any brain work must be of the easiest description. The questions relating to food and drink are manifold. In a large number of cardiac conditions, characterised by the presence of dropsy, a dry diet is of the greatest value, and the use of the smallest quantity of fluid possible is helpful. There are, however, many conditions, more especially of renal inadequacy, which forbid such drastic measures and render it necessary to put the patient on fluid food. Abundant rest, accompanied by some exercise, will be of utility. In the worst cases absolute confinement to bed is necessarily imperative, but even under such circumstances exercise may be obtained. It naturally falls into three categories. There is, in the first place, purely passive exercise, which may be given by means of massage. The utility of this method cannot be overestimated. Not merely does it empty the lymphatic spaces and accelerate the return of the contents of the lymphatic and venous vessels towards the heart, but it assists the metabolic processes in those parts of the system to which it is applied. Exercise, partly passive and partly active, may be obtained by means of the resistance exercises introduced by the Schotts,[40] and described in most of the recent works on diseases of the heart. Such resistance exercises are of very considerable benefit in the treatment of cases of heart disease presenting less alarming features than those just referred to. Active exercise may be employed in a variety of ways. In serious cases the exercise must be gentle and had best be confined to walking on level ground; in those which are of less severity gentle hill-climbing will be found useful, while the use of the cycle may be safely recommended. Closely associated with this subject is the stimulation of the system through the skin by means of baths.

The treatment of heart disease by means of baths is by no means of recent introduction, inasmuch as it was advocated by Hope.[41] It is only within the last few years, however, that this method of treatment has come into popular favour, and this is due chiefly to the work of Beneke,[42] Groedel,[43] and the brothers Schott.[44] The method is carried out very thoroughly at Nauheim, on the north-east slopes of the Taunus Mountains, in the Grand Duchy of Hesse. At this charming little place a number of springs arise from a depth of nearly 600 ft. below the surface; these fall into two groups, one of which is used for internal administration and the other solely employed for baths. The springs employed for the baths have a temperature varying from 82° to 95° F. and contain from 20 to 30 parts of sodium chloride and from 2 to 3 parts of calcium chloride in 1000, along with smaller proportions of potassium, lithium, magnesium, strontium, barium, iron, manganese, zinc, bromine, and arsenic, but they also contain a very large amount of carbonic acid, amounting in weight to almost 4 parts in 1000, and by volume 1340 in 1000. As baths these springs are employed in three ways—simple brine baths, effervescing baths, and effervescing current baths. Of these the first are employed at a strength of 15 per 1000 of sodium chloride and 1 per cent. of calcium chloride at a temperature of 94° or 95°, the carbonic acid being previously allowed to escape. The strength is gradually increased day by day and the temperature modified according to circumstances. The effervescing baths contain the full amount of salts and gas, the temperature being varied to suit individual requirements. The effervescing current baths are similar to the last mentioned in all respects save one, the water being allowed to stream into and out of the baths while it is being used. The Nauheim baths may be closely imitated without difficulty by means of Sandow's tablets. There cannot be the least doubt as to the powerful action of these baths under physiological conditions or as to their beneficial effects in some morbid states. The simple saline baths seem to have no influence beyond that of ordinary water at the temperature which is employed; that is to say, when the temperature is high the pulse becomes somewhat more frequent and more bounding, without any perceptible change in the condition of the heart. The effervescing baths in health cause a fall of the pulse-rate, an increase in its volume and an elevation of its pressure. Similar effects are produced in many conditions of disease. The effervescing current baths give rise to analogous effects, which, however, are somewhat more marked. So far all are agreed, but a considerable amount of controversy has raged round the size of the heart on percussion. My own observations, both at Nauheim and by means of imitations of the baths in this country, have convinced me that the apparent size of the heart is reduced by means of these baths, but that this apparent reduction of the cardiac dulness is produced by any actual diminution in the size of the organ has yet to be proved. It therefore seems to me that the suggestion of A. Morison,[45] previously referred to, is correct.

While there are differences of opinion as regard the results of these baths upon the apparent size of the heart, there can be none in respect of the beneficial results which accrue from the Nauheim treatment in suitable cases. Instances of cardiac weakness and dilatation, whether from depression, general disease, or over-strain, are certainly those which gain most. Many other conditions, however, such as cases of approaching breakdown in middle life and early disturbances of compensation in valvular disease, are also much improved by a course of baths. The greatest care must be employed in the selection of suitable cases. There can be no doubt that in many serious disturbances they will do more harm than good. The mode of action of these baths has been variously explained. By Schott,[46] for example, it has been asserted that increased tissue change is caused by a greater power of absorbing oxygen by the cells, possibly from the passage of gas through the skin, so as to come in contact with the tissues and stimulate the arterioles and capillaries. He also allows that there is probably a reflex stimulation of the heart producing more complete and thorough contraction. Broadbent[47] is of opinion that there is more probably a physiological dilatation of the capillaries in the skin so that the resistance to the blood is lessened and the left ventricle is unable to complete its systole. A. Morison[48] regards the action as being mostly reflex, but he is of opinion that the mere act of bathing is to be regarded as a form of gymnastics with a certain amount of influence over the circulation. With these views I practically agree.

Besides these various measures there are to be considered the special medicinal remedies which act directly upon the circulation. Almost all drugs which directly affect the heart and blood-vessels are to be found in Schmiedeberg's great group of nerve and muscle poisons. These various substances produce effects which vary very greatly, both in regard to the doses which are given and the time which elapses after administration. Many of them act as stimulants or tonics in small doses, while others act as sedatives or depressants in larger amounts. Another important consideration is that cardiac stimulants must be distinguished from circulatory stimulants. Many drugs excite the activity of the heart while producing no influence on the rapidity of the circulation; others can bring about acceleration of the blood-flow while producing no effects of an exciting kind upon the heart. As it is, therefore, difficult to classify these poisons from a purely physiological standpoint it is more convenient to arrange them in pharmacological groups. The alcohol group is of the greatest importance in the treatment of circulatory affections. Most of the drugs belonging to it produce in moderate doses dilatation of the arterioles and acceleration of the heart, while in larger quantities they bring about depression of all the great vital centres, including those controlling the circulation. Whether acting directly upon the heart muscle or indirectly through the nervous mechanism ethyl alcohol in almost any of its numberless forms acts both as a stimulant and as a food.

Ether is a powerful stimulant while chloroform is a most useful sedative, and chloral, although powerfully depressant on account of the large amount of chlorine in the molecule, is of importance as a hypnotic. Paraldehyde, sulphonal, and trional are the hypnotics belonging to this group which are most worthy of confidence. Closely associated with the alcohol group is that of the nitrites. These drugs, which owe their introduction to Lauder Brunton, are of world-wide renown for the purpose of reducing blood-pressure by dilatation of the arterioles. The ammonia group contains several drugs which have long been employed as stimulants, but modern research has not adequately explained this empirical conception. Carbonate of ammonium and its preparations certainly raise the blood-pressure. Such drugs are therefore of frequent employment, especially in combination with cardiac tonics. The camphor group contains several remedies which have a powerful effect in stimulating the cardiac muscle, and remedies belonging to this class are accordingly useful aids in the management of many circulatory conditions. Substances belonging to the caffeine group cause some vascular stimulation and inasmuch as they produce a change in the muscle curve they may influence the heart. This, however, has not been proved. Being direct renal stimulants they are of much importance when dropsy is present. Lastly, that most valuable class of drugs containing digitalis and strophanthus, besides many which from their inferior value require no mention, must be considered. What has to be said of this group really belongs to the two drugs named, seeing that they form the type of the class. The singular "type" is used, not "types"; the reason of this is that the drugs are practically identical in their effects. Diminution of pulse-rate, increase of cardiac energy, contraction of arterial walls, and consequent elevation of pressure result from both. There may be somewhat less arterial contraction in the case of strophanthus; it is, however, doubtful, and anyhow it is but a question of degree. In their results upon cases of disease it seems to me that strophanthus is to be preferred when there is necessity for rapid action and where the digestive system is irritable. On the other hand, digitalis is more valuable when the kidneys are not acting adequately and where œdema is present. In the latter condition the infusion acts most usefully, probably from containing a relatively large amount of digitonin. Into the mode of action of these drugs, whether they exert their influence by means of the nervous system or directly by stimulating the cardiac and arterial muscular structures, it is not expedient to enter. Suffice it to say that this point has not yet been cleared up.

In addition to all these means there are such important measures as evacuation, in which the employment of mercury is of prime importance, blood-letting, local and general—a method too much neglected—removal of fluid, whether by aspiration or by Southey's tubes, and counter-irritation by various agents. Each and all of these methods may be of the highest value. In recent years the treatment of cardiac affections has owed some brilliant results to serum-therapy. As has already been mentioned, micro-organisms are present in all cases of acute endocarditis, and it follows that the hard-and-fast line which used to be drawn between ulcerative or malignant and simple or verrucose endocarditis is no longer valid in its former meaning — in other words, the distinction is now clinical, not pathological. In certain infective cases cultures of the blood have revealed the presence of organisms, but, on the other hand, instances equally grave have given negative bacteriological results. The interesting point is this, that whether there has been a positive or a negative result on cultivation the employment of anti-streptococcic serum has in cases which would hitherto have been hopeless produced a fortunate result. An example of this condition was recently brought under my notice by one of my friends, who kindly asked me to see the patient with him. Although presenting clinical features strongly suggestive of infective endocarditis the blood was sterile, yet the use of Behring's serum was followed by rapid improvement leading to recovery.

Passing the various acute diseases by without further reference let me bring these somewhat rambling remarks to a termination by grouping the different varieties of chronic heart-disease into two classes according as the lesion has been adequately compensated or the circulation manifests disturbance of its equilibrium. In the former group, comprising the less serious cases of heart disease, *nimia diligentia* must be our motto; the "masterly inactivity" of a great statesman finds here a suitable field. Watchful care must no doubt be exercised in respect of all the general surroundings of the patient, that have already been examined, but the time of action has not arrived. While employing every means to ensure environment and occupation suitable for the conditions it will probably seem advisable to prevent the patient becoming a valetudinarian. It is far otherwise when there is inadequate compensation and the distressing features of failing circulation develop. Under such circumstances every measure calculated to strengthen the heart, to elevate arterial pressure, to aërate the blood, to remove excessive fluid, to improve the nutrition, and to stimulate the nervous system must be invoked. To do this is a task that will often tax all the energies of the physician and call forth all his ingenuity. He will, however, frequently find his reward in the recovery of some one,

> "Who scarce had pluck'd his flickering life again
> From halfway down the shadow of the grave," [49]

and he will find it, in the storm and stress of circumstances, to be a solace to follow the poet's advice:—

> "Æquam memento rebus in arduis
> Servare mentem." [50]

Inaugural Address
ON
SOME RUDIMENTS OF INTESTINAL SURGERY.

Delivered before the Midland Medical Society at Birmingham on Oct. 20th, 1898,

BY FREDERICK TREVES, F.R.C.S. ENG.,
SURGEON-IN-ORDINARY TO H.R.H. THE DUKE OF YORK; SURGEON TO THE LONDON HOSPITAL.

GENTLEMEN,—Anyone who still persists—on such an occasion as the present—in giving exclusive prominence to abdominal surgery cannot but be reminded of the fable of Æsop which relates to the "Belly and the Members." It will be recollected that in that parable the members complained that their interests were not duly recognised, and that the pompous and overbearing attitude assumed by the belly was inconsistent with its intrinsic importance and with the rights and privileges which the members claimed as portions of their body politic. So far as the corporation of medicine is concerned it may be argued that enough for the present has been said about the abdomen and its concerns, and that it is time we returned to the needs of the extremities. In begging, however, that you will allow me to limit my remarks this evening to that perhaps over-exalted subject, abdominal surgery, I may urge that the extra-visceral parts of the body have had an almost exclusive monopoly of surgical attention for many centuries and that Æsop—who was ignorant of even the fashionable exploratory incision—decided his fictitious quarrel in favour of the belly. I would wish to deal solely with so much of this great subject as concerns the intestines and with such details in that department as may be of some present interest.

As a preliminary and introductory matter I may assume that all surgeons who have concerned themselves with intestinal surgery must be growing sceptical in regard to the alimentary canal of man and its fitness for its reputed functions, and must be in doubt whether it deserves the encomiums which have been lavished upon it as an efficient work of nature. The actual body of man seems to have changed but little since his first appearance on the earth, but the environment of the man has changed in the meantime to an extent beyond all reasonable conception. Now it is a question if the alimentary canal has adapted itself to this latter change. It is a question if the human digestive organs have progressed with the times and have advanced with that progress of events which has raised man from a clever brute to a cultured epicurean. It is a question, indeed, if our stomach and intestines are, to use a common expression, quite up to date or are quite adapted to the

enlightened individual they serve. The naked cave man scrambled out his life some thousands of years ago and was contemporary with the long extinct cave bear and cave hyæna, yet his skeleton differs in no essential from the skeleton of the modern dandy who, arrayed as Solomon in all his glory, suns himself to-day in Rotten-row. A nineteenth-century public dinner would probably have confined the cave man to his cave for many sorrowful and painful days and if the modern alderman had to dine on badly cooked hyæna meat torn from the bone by his own incisor teeth, he would possibly find himself in a few days upon the operating table. Yet the same alimentary canal has had to do duty for the two specimens of humanity and for the two types of feast. It is no matter of wonder that it has failed somewhat in the herculean effort of adaptation. That it has not wholly succeeded is evident by many signs. If the cave man could return to earth and could travel by rail from London to Birmingham he would notice that almost every field by the way had erected in it an isolated wooden hoarding on which was painted a conspicuous inscription. From a certain repetition of these inscriptions he might gather that the painted words were incentives to religious fervour or that they were patriotic expressions calling the traveller to deeds of heroism and virtue. He would be pained to learn that they were merely advertisements of aperient pills.

It would appear, indeed, that these common objects by the traveller's way show that the cry of the people is not so much for light and leading as for laxatives. It is a curious comment upon the unfitness of the alimentary canal for its simplest duties that the animal, the vegetable, and the mineral kingdoms have been ransacked to provide incentives to peristaltic movement. The discovery of a new laxative would excite more public interest than the discovery of a new planet, and the habit of aperient drinking must rank in the annals of intemperance as but little less enthralling than the vice of the tippler. A further suggestion that the present type of alimentary canal is becoming obsolete is provided by the fact that in the literature of medicine a singularly prominent place is given to diseases of the stomach and intestines. The name of these maladies is Legion and in certain sections of the community dyspepsia can hardly be regarded as an abnormal condition. It is safe to say that among the so-called cultured classes one man in ten is "on a diet," and one woman in ten is "living on aperients." As for the liver it retains a place in our economy as a thing compounded of mystery, meddlesomeness and inefficiency. While some patients speak of their livers with a certain amount of awe, others refer to that organ with a degree of familiarity which is almost irreverent. With many the liver is a kind of fetish which has to be humoured and appeased, and no appeal to a medical man is more earnest than the prayer for "something to touch the liver." By others the liver is spoken of as if it were a piece of defective machinery and is alluded to in terms which would be suitably applied to a motor car or a cheap watch. It is complained that the organ is always "out of order," that it "will not act," that it is perpetually in need of something to make it act, that it is "sluggish," that it is easily "upset."

While the laity talk of their livers with an exactness which is based apparently upon most familiar acquaintance, the physician has not yet acquired a sufficient knowledge of that organ to enable him to even define precisely what is meant by "biliousness" or to give any reasonable scientific account of a "bilious attack." Time will probably show that the liver has played the part of a pampered charlatan and that its reputed powers are to no little extent based upon a great physiological fraud. Wherever the truth might lie, it would appear evident that this much-physicked organ is not competent to deal with the requirements of the alimentary canal of modern man, or at least that it performs its duties in the halting manner of a worn-out machine.

How things will fare with us in the future it is hard to say, but some hope of amendment is held out by the knowledge that nature appears to be both ready and ingenious in modifying structure to meet individual requirements. One notices, for example, amongst mammals what extraordinary and probably satisfactory experiments have been tried with the cæcum. The ornithorhynchus has a mere apology for a cæcum; the ursidæ have no cæcum at all, while many of the herbivora have cæca of immense proportions which apparently play an essential part in digestion. The two-toed ant-eater seems to have been in doubt as to whether it should accept the mammalian cæcum or content itself with the double cæcal appendages of certain birds, and to prevent any inconvenience from its indecision it has provided itself with three cæca—one of the mammalian form and two of the type met with in certain birds. The vulpine phalanger has been very decided in its appreciation of the cæcum and has possessed itself of an appendage which is twice the length of its own body.

In the matter of the stomach nature has proved to be most accommodating. The blood-sucking bat, or desmodus, living as it does on a highly digestible food which requires little more than storage, has almost solved the problem of how to live without either stomach or intestine. The fruit-eating bat—the pteropus—has turned its stomach upside-down so that it might digest its food in comfort while hanging head downwards. The kangaroo has a stomach precisely like our large intestine—i.e., arranged in sacculi so that its food may be packed away in small parcels and thus not incommode the animal when taking its prodigious leaps. The ruminant stomach appears to have been the outcome of an unattractive and bulky diet on the one hand and on the other hand of that passion for leisure and for reflection after meals which is so well marked in the common cow.

Without multiplying examples of apparent experiment and adaptation, one might be permitted to speculate as to the future form of the digestive canal of man. The human being is becoming toothless, and when it is recognised that a conspicuous function of the teeth is merely to provide material for the undoubted ingenuity of the dentist they will probably be allowed to go. Recent operations in which the entire stomach has been excised without any very gross inconvenience to the patient would seem to suggest that one might possibly dispense with our present type of stomach. Our intestine is probably unnecessarily long and the removal of considerable portions of it has done no more than add to the comfort of those individuals who have recovered from the operation. One patient of mine, who was the subject of congenital stenosis of the lower bowel, has been entirely relieved by the removal of the anus, rectum, sigmoid flexure, and descending colon. The child's large intestine is in this case represented by the ascending and transverse colon only, very much to the convenience of the patient. The frequency with which the sigmoid flexure is involved in mechanical difficulties and the common occurrence of cancer in the rectum would suggest that the terminal part of the bowel is becoming effete and may be regarded as degenerate by any pathological Max Nordau. As a matter of simple speculation it may be surmised that the coming man will be quite edentulous, that he will have a less enigmatical liver and no gall-bladder, and that his intestine will be considerably shortened and—it is to be hoped—considerably simplified. Extreme refinement in the selection of food materials and an exquisite cultivation of what is termed a "palate" may lead to an elongation of the œsophagus and to the development of taste organs along its entire length. In the place of the present stomach it is probable that the edentulous man will develop a gizzard. A gizzard would appear to be a labour-saving organ which is to be depended upon, and which is little liable to get out of order. A gizzard would probably be a great comfort to the over-worked man of business and to the seeker after pleasure who spends much of his life in continental hotels. The ruminant stomach has many attractions. Its size would make it popular with the operating surgeon, and its leisurely method of disposing of its contents suggests intervals of calm in the rush of modern existence. A ruminant stomach in a human being would, however, be inconsistent with the exclusively human habit of after-dinner speaking, and the actual act of rumination would no doubt be inconsistent with the amenities of the modern drawing-room.

To leave these matters of speculation and to enter upon subjects of present interest I would venture in the first place to allude to certain features connected with intestinal obstruction. The morbid anatomy of this affection has been very elaborately treated by many writers, and it is probably safe to assume that our knowledge of the mechanism of obstruction of the bowel is, in its main particulars, practically complete. From a clinical point of view, a proper appreciation of this common trouble is a little obscured by the prominence given to the actual item of the obstruction. In a fatal case of acute intestinal obstruction the undoubted occlusion of the bowel is by no means either the most serious or the most essential element in the progress of events. In a really acute case death will

Digitized by Google

take place within seven days, and it may almost be said that the fatal issue is in small part due to the fact that the lumen of the bowel is occluded. Obstruction of the bowel *per se* is not an acutely serious thing. The intestine may be blocked for a week, or for two weeks, or even for three weeks, and yet no very distressing or very alarming symptoms may attend this circumstance. In a fatal case of acute intestinal obstruction it can hardly be said that death is due directly to the obstruction. The complete closure of the bowels for a period of, say seven days, is not in itself an accident to cause death. Moreover, the clinical manifestations in a case of acute intestinal occlusion are in large part due to conditions other than those directly arising from the obstruction in the lumen of the gut. Finally, there is a period in the progress of such a case as we are considering in which the relief of the obstruction will not save the patient's life. Those who like to speak in paradox are almost justified in saying that in fatal cases of intestinal obstruction the patients do not die from intestinal obstruction. The interest of this matter extends, however, beyond a mere play upon words, and it can be shown that an undue prominence given to the mere fact of the obstruction is apt to distort both the clinical conception of the disease and the proper view of its treatment.

In the course of a case of acute intestinal obstruction it is possible to recognise three stages. In the first stage—or that of the onset of the trouble—the symptoms are those of intense abdominal pain, collapse, and vomiting. We will assume that the lesion is represented by the snaring of a loop of ileum by a peritoneal band. The symptoms in question, however, are in no way due to the fact that the bowel has become abruptly blocked. They depend upon the circumstance that a sudden and intense impression has been made upon exquisitely sensitive abdominal nerves. The symptoms must be classed as purely nervous. The vomiting, for example, is reflex and has no connexion whatever with the accidental fact that the bowel has become occluded. The symptoms which mark the onset of a case of acute intestinal obstruction have little or no diagnostic character. They are symptoms which attend all sudden and intense painful impressions upon important visceral nerves, and have been collectively described under the title of "peritonism." They are symptoms common to a series of intra-abdominal accidents. In the absence of any determining feature in the patient's history these clinical phenomena may equally well mark the passage of a gall-stone, the torsion of an ovarian tumour, the perforation of an ulcer of the stomach, or the rupture of a pericæcal abscess. They are nervous symptoms produced by a common nerve lesion and their interpretation can proceed no further than this—there has been an abrupt and intense impression made upon some part of the abdominal nerve plexuses. We have all seen cases in which perforation of the stomach or the appendix has been mistaken for intestinal obstruction and *vice versâ* and cases in which the lesion found in an early operation has had no kind of relation to the trouble suspected or assumed.

In what may be termed the second stage in a case of acute obstruction the symptoms attain more individuality and depend without doubt mainly upon the mechanical obstacle in the bowel. The pain is to a large extent due to disordered and futile peristaltic movements, the absolute constipation depends upon the blocking of the intestine, and the persistent vomiting is in the main due to the same cause. The character of the vomit, however, shows that another factor is being introduced into the circumstances of the case in the form of rapid decomposition of the intestinal contents. This depends, of course, upon the unnatural retention of those contents in the bowel and probably in a still larger degree upon vascular and other changes in the intestinal wall. The vomited matter becomes offensive and acquires an odour which for want of a standard of offensiveness may be called stercoraceous. Fæculent or fæcal vomiting—by which I assume is meant the ejection of fæces—I have not met with in acute obstruction. Finally, there is an increasing distension of the abdomen. This is largely due to mere accumulation, to mere inability of the contents to escape. The meteorism in intestinal obstruction is, however, in great part due to vascular changes in the bowel wall. This fact has been fully demonstrated by experiments upon animals and by pathological observations in man. It is well illustrated by the distension of the twisted loop in volvulus of the sigmoid flexure. The most severe case, indeed, of meteorism of the small intestine which has come under my notice was associated with no mechanical obstruction in the gut but with thrombosis of the superior mesenteric vein.

Last of all, in the third or final stage of acute obstruction the symptoms have little to do with the actual obstruction as such. They are the symptoms of poisoning and the patient who dies unrelieved dies poisoned. The septic matter which leads to his death is derived from his own intestine. It is the rapid onset of septicæmia which makes the operative treatment of acute intestinal obstruction so futile in the majority of cases. In many and many an instance an accurate diagnosis has been made, an early incision has been carried out, and the cause of the obstruction has been readily discovered and removed. The abdomen is closed and the patient dies. I remember one very painful example of this sequence of events. The patient was a man of middle age; the operation was performed forty-eight hours after the onset of the attack. A strangulating band presented itself the moment the abdomen was opened. It was divided without difficulty and the parietal wound was closed. A more favourable case could hardly have been conceived, yet the patient died with septic manifestations and the necropsy revealed no breach in the bowel and no gross peritonitis.

Those who wish to advance the therapeutics of intestinal obstruction must first of all grapple with this terrible element of intestinal septicæmia. Surgery wants a Lister who will teach us how to overcome the process of decomposition in the bowel. The lesion of the bowel need be by no means grave, the operation of dividing an easily discovered band cannot be considered to be severe, and yet the patient dies. I am quite aware that in a large proportion of these cases there is infection of the peritoneum to a degree which may lead to death and yet produce few of the naked eye manifestations of peritonitis, but the infection starts from the bowel and in the bowel the process of antisepsis must start. The intestine has some power of acquiring immunity against this septicæmia, as is made evident in cases of chronic obstruction of the bowel, and one meets with slighter grades of this self-poisoning from which the patient makes an easy recovery. Such milder forms are often seen in instances of fæcal accumulation. As soon as the fæcal mass has been removed there is often some fever with a mild degree of collapse and possibly nausea or even vomiting. As a rule such manifestations vanish in a day or so. The stomach seems not to lend itself to this form of blood-poisoning and extensive accumulations may take place in that organ and lead to no septic effects. The colon, too, would appear to possess a natural immunity up to a certain point, but in the lesser bowel the process is uncontrolled, desperate, rapid, and almost hopeless.

From a practical point of view, the treatment of acute intestinal obstruction appears to me to demand two things of the surgeon—(1) an early operation and (2) the evacuation of the bowel after the strangulation has been relieved. The first of these two measures will, I imagine, be allowed by all to be commendable. I do not urge that the opening of the abdomen in these particular cases is a trifling measure, but it is infinitely trifling when compared to the mere standing by with folded hands to await the remote possibility of spontaneous cure. The so-called medical treatment of these cases is a relic of the dark ages and must rank with the "faith cure" and the medical treatment of a dislocated hip.

With regard to the second proposition it appears to me that in a certain sense the real danger to life lies rather with the poisonous material in the intestine than with the actual obstructing cause beyond its walls. As I have already said, the patient is dying not because his bowel is occluded, but because the distended gut above the obstruction is producing a poison which is sapping his strength. It has unfortunately been too many times demonstrated that the successful relief of the obstruction will often fail to save life, and, indeed, it is of more moment to relieve the patient of the trouble within his bowel than of that which is without it. I have in all cases of acute intestinal obstruction with which I have had to deal in recent years not considered the operation complete until I had, as a matter of routine, emptied the bowel. This is conveniently done by bringing the most distended coil to the parietal incision and evacuating it by means of a small glass tube which is inserted into the gut and secured to the bowel wall by a single encircling thread. I have had no difficulty in closing the small artificial anus by a subsequent operation carried out some weeks after the original proceeding. I can certainly

Digitized by Google

state that this measure has had the effect—in my own practice at least—in reducing the mortality of this formidable measure to one-half of its original rate.

Some time ago, when collecting records of cases of acute intestinal obstruction treated by operation, I was struck by the fact that by far the best results attended the instances in which the surgeon had simply performed enterostomy—that is to say, in which he had made a small abdominal incision, had drawn out the first distended coil which presented itself, and had opened it and fixed it in position. In this remarkable series of cases the obstruction had been ignored and had not even been sought after and evidence was lacking to show what had happened to the snared bowel after the operation. I am quite aware that among these cases there are probably some in which there had been an error in diagnosis, but the number of examples in the series is too extensive to allow this possibility to disturb the conclusion which is forced upon those who will critically examine the evidence. In my opinion, the operation for really acute intestinal obstruction is not completed until the bowel has been evacuated of its contents. This measure of treatment is by no means new; it was most vigorously advanced by Travers in his remarkable work on the intestine which was published over eighty years ago. Travers supported his views by experiments upon animals and by the observation of many cases in the human subject and he elaborated his proposition by arguments which have not been affected by the scientific advances of a century.

To appreciate and deal with septic processes within the bowel must be one of the very first rudiments of intestinal surgery. The teachings of Lister have led to a revolution in the surgeon's art which is still a matter of amazement. Antiseptic surgery, however, as we employ the term, concerns itself mainly with the prevention of forms of infection in which the septic germ is introduced into the body from without. Antiseptic surgery has practically left untouched those forms of infection in which the septic element is in a certain sense introduced into the system from within. I allude specifically to those grave and often fatal conditions of septicæmia in which the patient is poisoned by the products of decomposition in his own intestine. I have just alluded to such infection in connexion with acute intestinal obstruction and without going fully into the matter I might add that in the majority of the examples of non-traumatic peritonitis, excluding the puerperal and tuberculous forms, the infection comes from the patient's own bowel. And with regard to that infection the remarkable fact is this, that the bacillus which appears to be most concerned in the production of this septicæmia is not a bacillus introduced accidentally into the bowel from without, but a bacillus which exists normally in the bowel in a condition of health. I allude, of course, to the bacterium coli commune. It is probable that the micro-organisms described under this name do not belong to one particular, definite species and that the term bacterium coli commune may be taken as a collective name for a group of bacteria which will probably be in time resolved into several different species. Anyhow this widely diffused bacillus exists normally in the intestine of healthy man and appears in the bowel a few hours after birth. It is found in all parts of the intestinal canal and at all periods of life. It is scarcely reasonable to assume that this invariable occupant of the healthy intestine is a mere noxious or useless parasite. It is more than probable that it is concerned in some direct or indirect way with the process of digestion. It would be indeed interesting to know how the phenomena of digestion would proceed in a sterile bowel. The bacterium coli may remain a perfectly harmless saprophyte; on the other hand it may rapidly alter its character and become possessed of intense pathogenic activity. It has been shown that in the majority of cases of perityphlitis the local inflammation is due to the bacterium coli commune which has escaped from the lumen of a diseased vermiform appendix. That extensive variety of peritonitis which takes its origin from the intestine — as illustrated by the peritoneal infection attending strangulation of the bowel — would appear to be in nearly every instance due to the micro-organism now under discussion. The virulence of the bacillus coli is subject to a quite extraordinary variability. An exaltation of its virulence may be due to an association with other organisms, pathogenic or non-pathogenic, but in most instances its morbid activity is excited by some change in the condition of the bowel itself. Diarrhœa, enteritis, cholera, typhoid fever are all capable of rendering this organism virulent, and the same may be said of the conditions attending fæcal accumulation.

Experiments upon animals make it probable that in man a moderate infection of the peritoneum with the colon bacillus from a healthy bowel would be harmless, while an infection by equal dose from a bowel rendered in any way unhealthy would induce peritonitis. Surgical experience would certainly support the suggestion. Klecki[1] has shown that the bacterium coli from the ileum is the most virulent, that from the jejunum ranks next, while that from the colon is the least potent for harm. There is no doubt that so long as the bowel wall remains intact, especially as regards the epithelium, little or no opportunity is afforded to the bacterium to escape from the gut. Artificial compression of a loop of bowel by an indiarubber ring (with or without ligature of the mesenteric vessels) will cause acute general peritonitis in dogs, as Klecki has demonstrated. The animals die in from twenty-four to forty-eight hours. The epithelium rapidly desquamates, the vessels dilate, and there is an abundant infiltration of the whole wall of the ligatured knuckle. The virulence of the colon bacillus within the loop is infinitely greater than that of the same micro-organism from an undisturbed part of the same intestine.

These facts suggest, by the way, that the handling of the bowel during an operation should be of the gentlest and that the evacuation of an obstructed loop is very desirable. On the other hand there is no doubt that the normal peritoneum has considerable powers of resisting an invasion of this particular bacterium. This protective power, however, would appear to be very soon lost if the delicate surface of the serous membrane be damaged. There is no doubt that the washing and scrubbing and rubbing to which the peritoneum was exposed while surgeons were under the influence of that fatal expression "the toilet of the peritoneum" led to many deaths. The peritoneum has remarkable powers of protecting itself if only the surgeon will permit it to exercise them. Save in a few exceptional instances the serous membrane is better able to deal with a moderate effusion than are the over-ready sponge and the futile and often fatal drainage-tube. I have noticed, moreover, that the peritoneum which has been subjected to repeated infections becomes in time almost immune. The operations which can be carried out with success in patients who have had repeated attacks of peritoneal inflammation are often almost beyond credence.

It will be evident from these few observations that the foundation of a rational intestinal surgery must be based upon a fuller knowledge of bacterial processes within the bowel. We need to know the function and purpose of the great bacterial horde which normally occupies the intestine, the circumstances which modify the virulence of those bacilli, and the conditions needed to apply the principles of antisepsis to the lumen of the bowel. One can, for example, imagine it possible that the introduction of some non-pathogenic bacterium into the intestine may beneficially influence by its growth the powers of micro-organisms which are already rampant in the bowel and uncontrolled. The impossibility of employing potent drugs, or what may be termed the usual antiseptics, to arrest certain decompositions within the bowel suggests the searching for such a measure as has just been mentioned. We want further information as to the conditions which increase and which diminish the power of the peritoneum to protect itself from invasion. I can imagine that in the future we may be able by artificial means to secure an immune peritoneum, and that this desirable condition may possibly be brought about by certain preliminary injections into the serous cavity itself. Among the minor advantages which would arise from a fuller knowledge of the common changes within the bowel I can imagine the discovery of an aperient which might be administered hypodermically. The need of a hypodermic aperient must have been apparent to all of us. It will probably not take the form of a drug, but rather of some product of bacterial change. Numerous experiments have been made upon animals with the colon bacillus and with its products, and especial interest attaches to those experiments in which the inoculations have been made hypodermically. It is evident that at present our knowledge of the subject is very crude and that our control of the bacillus coli is singularly imperfect. These injections in animals

[1] Annales de l'Institut Pasteur, 1895, tome ix., p. 710.

Digitized by Google

have led to very widespread and disastrous symptoms, but among them I notice the frequent mention of diarrhœa and it seems quite possible that further investigations may enable the bacteriologist to evolve a substance which will produce a diarrhœa which seems to be a feature in these hypodermic administrations.

We might now pass on to the consideration of certain points in connexion with the surgical handling of the intestine. In the first place it may be said that the common and useful operation of colotomy has been greatly improved within the last few years and has been rid of most of the after discomforts which made it at one time a measure to be greatly dreaded. The operation in the iliac region has entirely supplanted the colotomy in the loin, and the latter procedure has, indeed, become one of the rarest of abdominal operations. In inguinal colotomy pains have to be taken to select a proper spot for the opening in the sigmoid flexure, the bowel must be carfully fixed and, in my experience, the best results have attended the immediate opening of the gut, the contents being evacuated through a glass tube. Little or nothing is now seen in practice of two after-troubles which were at one time the bugbears of colotomy—viz., the contraction of the orifice, on the one hand, and the prolapse of the exposed bowel on the other. The average colotomy gives the patient but a minimum amount of trouble. In a large proportion of cases it is possible to secure a good action of the bowels every forty-eight hours, the artificial opening causing the patient but little or no inconvenience in the interval. If there be a degree of colitis present at the time of the operation it is true that the new opening may be the seat of a not inconsiderable distress. But in the average case the administration of a dose of mistura alba very early in the morning on alternate days will secure an ample evacuation of the bowel, followed by a period of immunity from disturbance. This much-to-be-desired result is rendered possible by very careful feeding and, above all, by the utmost attention to the wound. There is no doubt that the troubles attending colotomy, as performed some years ago, were in large measure due to neglect of the wound. A pad of septic tow and a dab of vaseline were placed over the bowel and the requirements of surgery were considered to have been thereby fully met. The gross neglect of the part was excused on the ground that the operation area was already septic. As a matter of fact, few complicated wounds respond more readily to careful treatment and assiduous attention than does the colotomy incision and the benefit to the patient from such care can hardly be over-estimated. I am convinced that the troublesome catarrh of the colon which was not uncommon after colotomy was very often due to the filthy condition into which the wound was allowed to pass, and that difficulty with the bowel in the form of prolapse was often dependent upon the same cause.

It is satisfactory, however, to note that the necessity for colotomy is rendered less frequent by the numerous opportunities for performing resection of the bowel—especially for cancer—and by the excellent results which have followed upon the operation of lateral anastomosis or short circuiting. The excision of a portion of the colon for malignant disease must rank as a most satisfactory procedure. The best results are obtained when the growth is situated in the sigmoid flexure or in such other part of the large intestine as may be provided with a free meso-colon. The least satisfactory cases are those in which the growth has involved a part of the bowel which is unassociated with a meso-colon and has a portion of its surface denuded of peritoneum. It is essential for success that the growth should be dealt with early and that the excision of the gut and of the associated meso-colon should be as liberal as possible. Indeed, it appears to me that among all the operations for the treatment of cancer by excision the removal of a portion of the sigmoid flexure for early epithelioma must rank as one of the most successful. In those instances in which the malignant growth—by reason of its position or extent—cannot be excised there are, happily, a fair proportion of cases in which a lateral anastomosis can be carried out and the patient be thus spared the inconvenience of a colotomy. Experience has shown that a considerable portion of the intestine can be thrown out of the circuit without apparent inconvenience to the patient.

Time will not permit of a discussion of the various methods whereby the bowel may be sutured, excised, or short-circuited. The name of intestinal sutures is legion. Indeed, the passion to invent a suture for the bowel seems to be almost as uncontrolled as the frenzy to invent midwifery forceps, pessaries, and needle-holders which has so long afflicted the medical profession. Many of the intestinal sutures are hopelessly bad because the thread passes through all the coats of the bowel and acts as a vehicle for conveying septic germs from the lumen of the gut to the peritoneum. Others are hopelessly complex and of interest only to those who find delight in ingenious puzzles. Not a few are the subject of periodical invention whereby the forgotten Jones-Robinson suture of 1800 becomes the quite original Smith-Johnson suture of 1898. To my thinking the best stitch is still the ancient one which includes a fine continuous suture of the mucous membrane and points of Lembert's suture which involve the other coats of the viscus. Certainly in the stomach no form of stitching is more convenient than this. Moreover, among the horde of intestinal needles the best is the milliner's needle which comes from the draper's shop.

Of the methods of uniting divided bowel, either after excision or in the performance of a lateral anastomosis, the best theoretically is without doubt the method of simple suturing. In practice, however, this can seldom be advantageously employed. The simple suture involves a great expenditure of time; the differences in the segment of gut above the stricture and that below it render straightforward suturing almost impracticable; the bowel at the suture line is very apt to kink. To cope with these difficulties there has arisen the remarkable host of plates, discs, tubes, cylinders, buttons, and bobbins which has so disturbed the peace of the surgeon who hungers after the "last new thing." Not a few of these appliances alternate between oblivion and rediscovery to the great hindrance of progress. For example, in 1882[2] I described a method of suturing bowel over a collapsible indiarubber bag which was sausage-shaped and was introduced into the ends of the gut to be united. It could be blown out into the form of a firm cushion and before the last stitches were introduced could be emptied and withdrawn. A little experience showed me that my bag was useless and I promptly discarded it. Now after a period of sixteen years an American surgeon, Dr. W. S. Halsted[3] rediscovers my useless bag and reproduces it with singular exactness. He believes this old-new procedure to be "better than any method hitherto devised," and so we step back sixteen years. Dr. Halsted also, by the way, expresses his conviction "that there should be a law compelling all surgeons to practise on animals the operations for circular suture of the intestine and for intestinal anastomosis." I hope this view will not commend itself to the legislators of this country. Many years ago I carried out on the Continent sundry operations upon the intestines of dogs, but such are the differences between the human and the canine bowel that when I came to operate upon man I found that I was much hampered by my new experience, that I had everything to unlearn, and that my experiments had done little but unfit me to deal with the human intestine.

Of the various appliances in vogue for the uniting of divided bowel I think the best is Murphy's button. It is very far from being a perfect instrument, but it compares at least very favourably with the other forms of apparatus which compete with it. The idea underlying the button appears to have originated sixty-two years ago in the brain of one Denans.[4] "He introduced into the upper and lower end of the (divided) gut a silver or zinc ring, thrusting it inwards about two lines from each end; he then brought the two ends together over a third ring, of which the two springs retain the external rings. The included ends of the intestine mortify and the rings thereby becoming unfastened are discharged by stool after they have united the serous surfaces in contact" (Chelius). I have employed Murphy's button in considerably over 50 cases with results which are certainly satisfactory. The button requires no elaborate preparation; it is always ready; its introduction is exceedingly simple and is effected in a few minutes. The two parts of the instrument may certainly jam, but I think that that accident is the result of careless handling. I have never known it to induce a gangrene which has extended beyond the limit of the button. The two definite and undoubted objections to the button are these—it may be indefinitely retained

[2] Transactions of the Royal Medical and Chirurgical Society, vol. xlviii., p. 55.

Digitized by Google

and its separation may be followed by contraction of the artificial opening. These two undesirable results are often in close relation to one another as cause and effect. In the cases of cholecystenterostomy in which I have used the button I have never known it to be retained and, so far as I am aware, the opening made has not undergone inconvenient contraction. In cases in which the button has been employed in the colon only I have never had it retained, but in some instances—a very small minority—there has been contraction of the new passage. In examples of gastro-enterostomy performed by means of this apparatus retention of the button for considerable periods or its absolute failure to appear at all seems to me to be the rule rather than the exception. In not a few instances there has been undoubted contraction of the artificial opening. In only 2 examples of gastro-enterostomy in which the button was retained has that instrument caused any trouble. In the first of the 2 cases I performed gastro-enterostomy upon a man, aged thirty-nine years, for pyloric obstruction due apparently to non-malignant disease. He had been ill a year at the time of the operation, which was performed on March 24th, 1897. He was at that time greatly emaciated and the stomach was very much dilated. He made a perfect recovery and subsequently gained 3 st. in weight. He had no further gastric symptoms of any kind. The button was never known to have passed. On March 14th, 1898, he was seized with severe epigastric pain after bicycling. In due course a fœtid abscess formed under the old scar. This was opened on March 28th and it rapidly healed. A skiagraph showed very distinctly that the button was still in the stomach. On April 16th I opened the stomach and removed the button, which was quite loose. It was black and rough, but still in working order. The patient's recovery was complete and he left the surgical home in three weeks in excellent condition and free from all gastric symptoms. In the second case the patient was a man, aged thirty-six years, with non-malignant obstruction of the pylorus and great dilatation of the stomach. Gastro-enterostomy was performed in June, 1897, followed by a speedy recovery. He kept in excellent health until March, 1898, when after a few days of abdominal pain an abscess containing fæces burst through the parietal wound. A fæcal fistula has since remained. In this case the button lodged in the lower ileum and owing to peculiar complications which I need not deal with it has only just been removed.

As an example of contraction of the colon after the use of the button I may mention the following case. A man, aged sixty-one years, who had had symptoms of chronic intestinal obstruction for some months, was seized with symptoms of acute occlusion of the bowel, attended by immense distension of the abdomen and stercoraceous vomiting. Laparotomy, performed in January, 1897, revealed an epithelioma in the centre of the sigmoid flexure. The urgency of the case and the great distension forbade any attempt at excision. I therefore effected an anastomosis, by means of a Murphy's button of the largest size, between the two extreme ends of the sigmoid flexure. The diameter of the button was 1½ in. Fluid fæces were passed before the patient left the table and he was at once relieved. The button, which had already been used in two previous cases, was passed on the twenty-second day. The patient was walking out of doors at the end of the fourth week. In March, 1897, he had regained his original weight and his bowels were acting well with aperients. I then performed a second laparotomy to remove the sigmoid flexure. Although only thirty-eight days had elapsed since the passing of the button I found the artificial opening I had made so contracted that it would do no more than admit my little finger. I removed the whole sigmoid flexure and united the descending colon to the rectum by means of the same button. This button was passed on the sixteenth day. The patient recovered rapidly and remains in sound and vigorous health.

The explanation of these cases of contraction, whether in the stomach or in the colon, is not far to seek. The button effects an opening between the two viscera by means of pressure gangrene. I have noticed that after-contraction has only occurred in cases in which the upper viscus was much dilated at the time of the operation. It is needless to say that in gastro-enterostomy in pyloric obstruction a dilated stomach is met with and in intestinal anastomosis for stricture the upper segment of the gut is apt to be enormously distended. After the operation the dilated organ contracts and consequently the newly made hole contracts. I can easily imagine that a hole in a dilated stomach made by pressure gangrene and of the size of half a crown may readily become an aperture of the size of a fourpenny-piece when the distended viscus has gradually contracted. It is therefore very desirable to have the viscera to be dealt with as empty as possible before the button is introduced. This end is very difficult to secure even to a partial degree. The stomach, for example, in old pyloric obstruction, even when kept washed out for many days, is slow to contract, and if at the time of the operation the viscus be still much dilated retention of the button and some inconvenient contraction of the new opening may be regarded as possible. This association between previous distension of a viscus and the subsequent contraction of the aperture made in it is of course by no means limited to Murphy's button. It applies to nearly every method in vogue for carrying out the operations now under discussion. Still, in spite of many drawbacks and many failures intestinal surgery has made within the last few years decided and substantial advances; but it will fall short of perfection until antiseptic surgery, which has so far penetrated only to the serous covering of the gut, has reached the mysterious and septic lumen which lies within the bowel wall.

SUMMARY OF GUNSHOT WOUND CASES TREATED IN NO. 2 NATIVE GENERAL HOSPITAL AT RAWAL PINDI.

BY CAPTAIN D. M. MOIR, I.M.S., M.B., C.M. EDIN.,
REGISTRAR NO. 2 NATIVE GENERAL HOSPITAL.

(Continued from page 1130.)

MARTINI-HENRY BULLET-WOUNDS.

1. MARTINI-HENRY bullets lodged in the tissues much more frequently than the Lee-Metford and much more deeply than the round balls. Consequently they were more difficult to find and also more difficult to extract, partly owing to their greater depth and partly owing to their being more deformed, more jagged and flattened.

2. Owing to the Martini-Henry bullets being more deeply lodged there was a greater tendency for them to shift their position, to wander in the planes of the deep muscles or inter-muscular septa.

3. Major Beevor's Roentgen rays apparatus proved of the greatest use in localising the site of and in confirming the presence or absence of bullets in the tissues. In a couple of instances men were received with only a single scar, that of the wound of entrance; but there was no reliable information available as to whether the bullet had been subsequently extracted. With the x rays it was a simple matter to demonstrate that no foreign body remained lodged in the limb or part affected.

4. Owing to the introduction of foreign bodies or septic material, owing to the greater trauma to the tissues, or in consequence of increased manipulative interference in extracting deeply-seated and encapsuled projectiles the wounds suppurated, sinuses were common, and the patients were longer in hospital. There was more damage done to important structures, so the wounded were disabled for a longer average period.

5. Wounds of the lower extremity in this series number double those of the upper. Case 70, in which a bullet travelled half way round the pelvis without injury to the viscera, is one of considerable interest, as is also Case 193, in which a bullet perforated the chest, lung, and shoulder-joint and fractured the head of the humerus.

CASE 70. *Gunshot wound in the abdomen, V., 3.*—The patient (1st Battalion 2nd Gurkhas) was wounded at Maidan by a Martini-Henry bullet fired at a range of about 600 yards. It struck him on the right buttock, traversed the pelvis, and emerged in the right groin close to the os pubis. After piercing the skin the bullet dropped down inside his trousers, not having sufficient force to find its way through his clothes. The wound healed readily, so that he was able to walk a little eight days after the injury. On admission here (Dec. 1st, 1897) both wounds were quite healed, the scar of entrance being round, that of exit being linear and 1 in. in length. It would seem that the bullet entered the sacro-sciatic foramen or perforated the ligaments and then passed round

Digitized by Google

the brim of the true pelvis and was directed along Poupart's ligament until it came out just above the spine of the pubes. In this way neither the bones of the pelvis nor the pelvic viscera were injured and the man had a most wonderful escape and a rapid recovery. On Dec. 13th he was discharged to duty at his depôt.

CASE 23. *Gunshot wound in the lower extremity, IX., 1.*—The patient (1st Battalion 2nd Gurkhas) was wounded at Dargai on Oct. 20th, 1897, by a Martini-Henry bullet fired from above while he was running at "the double." He was admitted here on Nov. 9th, at which time the entrance of the wound was healed. It was on the outer and front aspect of the left thigh close to the knee-joint. There seems to have been a suspicion that the bullet had lodged in the lower articular end of the femur owing to the joint being hot, inflamed, tender, and enlarged, with great limitation of movement. As the position of the bullet could not be accurately located, on Jan. 12th, 1898, a skiagraph of the limb was taken by Major Bamber and Major Beevor. This showed the bullet to be lying behind the tibia just below the insertion of the semi-membranosus muscle. It turned out that Major Beevor had taken a skiagraph of this case at Shinawari soon after the Dargai action. At that time the bullet was lying an inch below the head of the fibula and to its outer side. Consequently the bullet had travelled upwards and inwards across the back of the leg in the interval of about two and a half months. On the 15th the bullet was extracted from the muscles of the calf. Considerable difficulty was experienced owing to the peculiar jagged shape of the bullet, which had become encapsuled. A good deal of suppuration followed extraction of the bullet, involving a fresh incision and drainage; healing was therefore greatly retarded.

CASE 158. *Gunshot wound in the lower extremity, IX., 1.*—The patient (1st Battalion 3rd Gurkhas) was wounded in Tirah on Dec. 12th, 1897, by a Martini-Henry bullet which was fired at a range of about 600 yards. It struck him about the middle of the inner side of the left thigh and lodged. On admission here (Dec. 21st) the bullet seemed to be lying above the front of the shaft of the femur and under the quadriceps extensor. It could not be felt by introducing a probe into the wound, but there was a hard and tender spot about 3 in. from the wound of entrance in the situation indicated in the preceding sentence. On Jan. 12th, 1898, the limb was examined with the Roentgen rays and the bullet was stated to be lying close to the inner side of the femur and behind it at the same level as the wound of entrance. On the 14th under chloroform the original wound was enlarged and explored both in front of and behind the femur, but no bullet could be found, though a small piece of khaki cloth, half an inch square, was removed from the track of the wound. Another incision was then made further back, parallel to the femur and behind the adductor magnus, but no trace of the bullet could be discovered, although the back of the shaft was exposed and the surrounding tissues were thoroughly explored. The x rays were applied twice after this. On one occasion the bullet was said to be large and square, lying with its axis transversely across that of the femur on its inner side. On the other occasion it was alleged that three fragments of lead were scattered about at different levels on the inner side of and slightly behind the femur in the position described on the first application of the rays. On Feb. 15th the bullet could be distinctly felt lying in the position first suspected on admission and before the x rays were applied. An incision 2 in. long was made on the front of the thigh about the level of the entrance wound and to the outer side of the sartorius. The bullet was found encapsuled in the quadriceps extensor and it was difficult to dislodge owing to irregularities in its outline. It was flattened and spread out like a fan from base to tip. On one side it was smooth, but on the reverse it was very rough with irregular turned-up edges. In front it was quite sharp-edged. Its length was 1⅜ in. and ⅞ in. was its greatest breadth. After this the patient did very well and the wound healed readily. On April 4th he could walk without a limp and without any support, so he rejoined his regiment next day.

CASE 178. *Gunshot wound in the lower extremity, IX., 1.*—The patient (36th Sikhs) was wounded at Bagh by a Martini-Henry bullet on March 24th, 1897, which entered the front of the middle of the right thigh and lodged. He was examined with the Roentgen rays at Bagh and the position of the bullet was determined. It was extracted through an incision at the back of the thigh on the third attempt, the first two occasions having proved unsuccessful. On arrival here (Jan. 22nd, 1898) the wounds were granulating well, but the knee was rather stiff. On Feb. 28th two bits of coarse blue cloth, ½ in. by ⅜ in. and ⅜ in. by ¼ in., were removed through the posterior wound. On March 24th both wounds were soundly healed. The knee was rather stiff and the patient limped a little. On the 26th he was sent on four and a half months' sick leave.

CASE 129. *Gunshot wound, XII., with injury of the external popliteal nerve.*—The patient (8th Mountain Battery) was wounded in Tirah on Nov. 16th, 1897. A Martini-Henry bullet hit him on the outer side of the left thigh a little above its middle and passed inwards and backwards to emerge in the centre of the popliteal space. On admission here (Dec. 19th) the entrance wound was 1¼ in. long and ¼ in. broad. The exit wound was much larger, 3 in. long and 1 in. broad. He complained of much pain in the leg and foot owing to the external popliteal nerve having been injured and involved in the cicatrix. On Jan. 20th, 1898, he was sent on three and a half months' sick leave.

CASE 183. *Gunshot wound in the lower extremity, IX., 1.*—The patient (13th Bengal Lancers) was wounded at Shabkadr on August 8th, 1897, by a Martini-Henry bullet, which entered the right buttock on a level with the great trochanter and lodged. On Sept. 1st an unsuccessful attempt was made at Peshawar to extract the bullet from the front of the thigh under chloroform. He was transferred here on Jan. 26th, 1898, for examination by the Roentgen rays apparatus. The bullet must have shifted its position on the journey to Rawal Pindi, because on admission here it could be so plainly felt on the inner side of the front of the thigh just internal to the scar of the former operation that the use of the x rays was unnecessary. On Feb. 3rd the bullet was extracted without much trouble. It was encapsuled under the sartorius and close to the femoral vessels and it had an irregular surface and flattened shape. On the 28th the wound had quite healed.

CASE 177. *Gunshot wound in the lower extremity, IX., 4, tibia and fibula.*—The patient (36th Sikhs) was wounded at Maidan on Nov. 9th, 1897, by a Martini-Henry bullet which passed through the right leg. It entered about an inch above the internal malleolus and passed out about an inch and a half above the external malleolus. At Kohat the exit wound was enlarged to allow of some fragments of dead bone being removed. On admission here (June 22nd, 1898) both wounds were open and discharging pus. On passing a probe a couple of inches up the track of the exit wound bare bone could be felt. Both tibia and fibula seemed to have united at the seat of the fracture and the ankle-joint had escaped injury. On Feb. 21st both wounds had healed. On March 14th he walked with the help of crutches. On the 26th much callus was thrown out at the site of fracture. The foot was in a good position and movements of the ankle were free. He could walk with the aid of a stick. He was sent on six months' sick leave.

CASE 4. *Gunshot wound in the lower extremity, IX., 1.*—The patient (1st Battalion 2nd Gurkhas) was wounded at Dargai on Oct. 20th, 1897, by a Martini-Henry bullet, which passed through the middle of the leg between the tibia and fibula without touching either bone. On admission here (Nov. 3rd) the wound was granulating satisfactorily. On the 29th he was discharged to duty at his depôt.

CASE 193. *Gunshot wound in the chest, V., perforating contents deeply; upper extremity, VIII., 4, humerus.*—The patient (12th Bengal Infantry) was wounded at Maidan on Dec. 1st, 1897, by a Martini-Henry bullet while retiring on rearguard duty. The shot was fired from a hill about 300 yards distant. The bullet entered his back on a level with the lower angle of the right scapula and about an inch to the right of the dorsal spine; it passed through the chest cavity upwards and outwards, then through the axilla, and emerged on the outer side of the right arm near the insertion of the deltoid. Air and blood came out of the chest wounds. The exit wound was large and irregular owing to the bullet having carried away a portion of the head of the humerus. Fragments of bone were removed from the exit wound while he was in hospital at Kohat. On admission here (Jan. 21st, 1898) the wound of entrance was healed, its scar being ½ in. long, and the wound of exit had completely healed. There was much thickening about the head of the humerus and the shoulder-joint was stiff. On March 9th all the movements of the shoulder-joint were limited, especially abduction, in spite of regular massage and passive movement. There was loss of sensation over the

Digitized by Google

cutaneous area supplied by the median and musculo-spiral nerves. The prehensile power of the right hand was very feeble. On the 31st prognosis was bad as regards service. He was discharged to his depôt at Bareilly to appear before an invaliding board.

CASE 14. *Gunshot wound in the upper extremity, VIII., 1.*—The patient (15th Sikhs) was wounded at Dargai on Oct. 18th, 1897, by a Martini-Henry bullet, which entered on the outer side of the right arm about an inch above the insertion of the deltoid. It passed inwards towards the median line and slightly upwards, and came out over the spine at the root of the neck behind. He was admitted here on Nov. 5th with a granulating wound and he was discharged to his depôt at the end of that month.

CASE 26. *Gunshot wound in the upper extremity, VIII., 1.*—The patient (2nd Battalion 4th Gurkhas) was wounded in Tirah on Oct. 28th, 1897, by a Martini-Henry bullet which entered the back of his left arm about the level of the deltoid insertion while his arm was raised. It traversed the back of the arm without injuring the humerus and emerged on the outer side at the junction of the lower and middle thirds. He was transferred here on Nov. 9th with a suppurating wound. On Dec. 17th he was discharged to duty at his depôt.

CASE 111. *Gunshot wound in the upper extremity, VIII., 5.*—The patient (No. 2 Derajat Mountain Battery) was wounded at Kharappa by a Martini-Henry bullet while he was holding up his hand as a signal. The bullet was fired at a distance of 700 or 800 yards, and struck the back of his left hand and lodged in the angle formed by the metacarpals of the thumb and index finger. It was extracted soon afterwards, but the wound did not heal readily and severe eczema supervened. On admission here (Dec. 6th) the discharge from the wound was lessening and the eczema on the back of the hand was gone. On Dec. 27th he was sent on two months' sick leave.

SNIDER BULLET WOUNDS.

1. From a review of these 11 cases of Snider bullet wounds the most noticeable thing is the severity of the effects produced, which greatly surpassed the results above described under the headings of wounds from Lee-Metford, Martini-Henry, and round bullets. In all of the Snider wounds recovery was slow or imperfect owing to suppuration and to severe traumatism.

2. In 9 out of the total bones were fractured. The Snider wounds gave the greatest proportion of fractures and also the most severe ones. The spherical bullet wounds had the next greatest number of fractures and the Lee-Metford wounds the fewest.

3. As regards the lodgment of projectiles this occurred in 4 out of the 11 Snider cases, as compared with 5 out of the 12 Martini-Henry wounds, and 13 bullets lodged in 12 of the 16 spherical bullet-wound cases.

4. As in the Martini-Henry series, the wounds of the lower extremities greatly outnumbered those of the upper limbs.

5. It is interesting to note that all 3 cases of bullet-wound of the lung survived. In the Lee-Metford case there was rapid and complete recovery in a fortnight, no bone having been injured; but the results were very different in the two other cases. In one (Martini-Henry) the shoulder-joint was opened and the head of the humerus was fractured, in the other (Snider) the glenoid angle of the scapula was fractured. The subsequent progress of these two cases was very similar. They were both received at Rawal Pindi on the same day, having been 52 and 55 days on the lines of communication after they were wounded; and they remained at No. 2 Native General Hospital for 68 and 69 days. The prognosis in both cases was much the same; one was sent before an invaliding board as permanently unfit and the other was given a chance of six months' sick leave in case he might recover sufficiently to be fit for further service.

CASE 174. *Gunshot wound in the chest, IV., 4.*—The patient (1st Battalion 2nd Gurkhas) was wounded in Tirah by a Snider bullet on Nov. 28th, 1897. The bullet struck the back of the left shoulder, smashed through the outer part of the scapula near its glenoid angle, passed through the lung and chest obliquely, and lodged under the skin in front of the head of the humerus, from which place it was extracted through a vertical incision which healed quickly. Emphysema occurred after the injury and the entrance wound proved troublesome. On his arrival here (Jan. 21st, 1898) the anterior wound was healed and only a small sinus remained in the line of the posterior wound. The movements of the shoulder were limited owing to pain and stiffness. On Feb. 19th the sinus was 1¼ in. long and showed no tendency to close. On March 9th a piece of cloth was found and removed while the wound was being explored. On the 28th the sinus had healed. Movements of the arm were slightly impaired, but this stiffness will wear off in time. Two days later he was sent on six months' sick leave.

CASE 100. *Gunshot wound of the upper extremity, VIII., 2.*—The patient (Jhind Infantry) was wounded in Waran on Nov. 16th, 1897, by a Snider bullet. The wound of entrance was just below the right acromio-clavicular joint. The bullet passed directly backwards just above the shoulder-joint, fractured the scapula, and emerged below the spine of the latter. On admission here (Dec. 4th) the wound of entrance was closed and that of exit was merely a small ulcer. The movements of the shoulder-joint were unimpaired. On Dec. 20th the wound of entrance, which was apparently soundly healed, broke down and the wooden plug of a Snider bullet was discharged in the dressings. On Jan. 4th, 1898, he was sent on two months' sick leave, the wound being quite healed.

CASE 179. *Gunshot wound in the upper extremity, VIII., 4, humerus.*—The patient (36th Sikhs) was wounded at Maidan on Nov. 24th, 1897, by a Snider bullet, which struck the outer side of his right arm about the middle, passed through the humerus, shattering it, and escaped just above the inner condyle. On admission here (Jan. 22nd, 1898) the exit wound was healed, but there was a drainage-tube passing from the entrance wound obliquely downwards across the arm to an incision on the inner side of the forearm, which had been made for drainage purposes. On the 31st the wound of exit had reopened and was discharging pus copiously on Feb. 8th. Under chloroform all the wounds were enlarged and the unhealthy granulations lining them were scraped off. A piece of lead ½ in. long and ¼ in. broad was found in the soft tissues and two sequestra of a larger size were removed through the entrance wound. The soft tissues were œdematous and infiltrated for 6 in. above and below the elbow, but the joint was not affected beyond its being rigidly flexed owing to the contraction of the biceps and brachialis anticus. There was no real union of the fracture in the shaft of the humerus, although a good deal of callus existed; accordingly the ends of the bone were rubbed together to stimulate union. Large drainage-tubes were inserted, the arm was put up in small straight encircling splints covered by two ordinary rectangular ones, and a tonic containing strychnine and iron was ordered. By the middle of March the humerus seemed to be uniting fairly well and at the end of the third week all drainage-tubes were removed. On April 5th union was firm in the humerus and the transverse line of fracture could be easily palpated owing to the thickening at that site. Most of the sinuses healed. On the 21st he was transferred to the depôt hospital of his regiment.

CASE 176. *Gunshot wounds, VII., perineum, genital, and urinary organs.*—The patient (36th Sikhs) was wounded at Gulistan on Sept. 13th, 1897, by a Snider bullet which entered the left side of the scrotum, splintered the pubic arch, and passed along the perineum, lacerating the corpus spongiosum and bulb and escaped near the anus. Pieces of the os pubis were removed by operation, urinary fistulæ formed in the perineum, and a counter opening was made in the right buttock. On admission here (Jan. 22nd, 1898) he had a bad traumatic stricture, but only one fistula *in perinæo*, and that was closed before the end of the first week in February. On April 3rd the stricture proved very obstinate, as might have been expected in so severe an organic stricture. Otherwise he was in excellent health, so he was sent on six months' sick leave.

CASE 58. *Gunshot wound in the lower extremity, IX., 1.*—The patient (2nd Battalion 1st Gurkhas) was wounded at Maidan on Nov. 3rd, 1897, by a Snider bullet which ricocheted off the ground before it struck him on the right buttock just above and behind the trochanter major. It lodged about 3 in. from the surface and was extracted a fortnight later. On Jan. 8th, 1898, the wound had completely healed and he would have been discharged to duty had he not been detained to act as a sick attendant on a comrade.

CASE 127. *Gunshot wound in the lower extremity, IX., 4, femur.*—The patient (1st Battalion 2nd Gurkhas) was wounded at Dargai on Oct. 20th, 1897, by a Snider bullet, which struck him on the outer and front part of the right thigh a little above the middle and passed backwards and inwards, fracturing the femur and emerging at the back of the thigh. The bullet then struck his kukri and fell to the ground. His thigh was put up in a long splint and he was

Digitized by Google

sent to Shinawari, where he remained for 8 weeks. On admission here (Dec. 19th) the exit wound was healed and that of entrance was closing, and the bone had united. On Jan. 8th, 1898, all wounds had healed and union was firm.

CASE 180. *Gunshot wound in the lower extremity, IX., 1.*—The patient (36th Sikhs) was wounded at Maidan on Nov. 23rd, 1897, by a Snider bullet, which entered the inner and upper third of the right thigh and lodged in the limb. An unsuccessful attempt was made at Maidan to remove the bullet, but it was extracted at Kohat on Dec. 9th after its position had been localised with the aid of the x rays. On admission here (Jan. 22nd, 1898) both wounds were soundly healed and there was only a slight limp in the man's gait. On Feb. 9th he walked well and on the 15th he was sent on six months' sick leave.

CASE 172. *Gunshot wound in the lower extremity, IX., 4, tibia and fibula.*—The patient (15th Sikhs) was wounded at Maidan on Nov. 6th, 1897, by a Snider bullet which struck his left leg about 2 in. above the inner malleolus from behind. It smashed the tibia badly and came out in front after breaking the fibula also. After a time he was sent to Kohat in splints, where the wound of entrance was opened up under chloroform on Jan. 8th, 1898. The exit wound appeared to have healed readily. On arrival here (Jan. 21st) there was a large healthy granulating surface about 3 in. long by 1 in. wide on the inner side of the leg above the ankle. There was a great deal of irregular thickening and callus about the lower ends of both bones and the ankle was stiff and tender. Sequestra were removed on the 26th and on March 10th, but the man remained very lame owing to "toe drop" of the great toe. On the 23rd there was a sinus 1 in. long and still bare bone could be felt. On April 17th he was transferred to his regimental hospital at Ferozepur.

CASE 175. *Gunshot wound in the lower extremity, IX., 2.*—The patient (15th Sikhs) was wounded in Tirah by a Snider bullet on Nov. 6th, 1897, at a range of about 150 yards. The bullet entered the lower third of the leg internal to the tibia and passed out directly backwards in a straight line. A bit of the shaft of the tibia was chipped off or injured, because some pieces of bone came away afterwards, but the shaft was not completely fractured. On transfer here (Jan. 21st, 1898) there was a comparatively small wound of entrance, in diameter that of a shilling, with a depressed cicatrix and a small sinus. The exit wound was healing well and was about 4 in. long and 2 in. broad. There was considerable thickening of the limb all round on a level with the injury. On March 1st the wound had been quite healed for the past fortnight, but there were now lameness and defective flexion of the toes; extension was not affected. On April 13th the sinus had almost healed and the patient was doing well. He was transferred to his regimental hospital at Ferozepur.

CASE 187. *Gunshot wound in the lower extremity, IX., 4, fibula.*—The patient (2nd Battalion 5th Gurkhas) was wounded at Bagh on Nov. 26th, 1897, by a Snider bullet, which entered the outer side of the right leg 3 in. above the ankle-joint and came out on the back of the limb about the same level, lodging in his puttee. It broke the fibula and some pieces of bone were removed later. On admission here (Jan. 27th, 1898) the wound of entrance was healed; a drainage-tube 1 in. long was in the exit wound and there was thickening over the lower third of the fibula, in which there seemed to be a small gap. On March 18th suppuration continued, healing was delayed, and non-union of bone continued. He was allowed to go about on crutches. On April 13th over an inch of the fibula was wanting. The probe entered the sinus of exit for an inch and a half and impinged on the free end of the lower fragment, which seemed necrosed. Next day he was transferred to his regimental hospital in the hills.

CASE 148. *Gunshot wound of the lower extremity, IX., 5.*—The patient (Jhind Infantry) was wounded in Tirah on Dec. 13th, 1897, by a Snider bullet which struck him on the dorsum of the left foot about 1 in. from the base of the little toe. It passed through the foot between the fourth and fifth metatarsals and emerged in the sole almost directly below the wound of entrance, lodging in the boot. The exit wound was considerably the larger, probably owing to the bullet forcing fragments of bone before it. He was admitted on the 21st with a freely suppurating wound. On Feb. 18th, 1898, a small sequestrum was removed. A week later he had a severe attack of eczema madidans on the wounded foot. On March 14th both wounds had healed and the eczema was cured. He was discharged to duty at his depôt next day.

CAVALRY CARBINE WOUND.

CASE 191. *Gunshot wound of the upper extremity, VIII., 5.*—This case differs from all the preceding in that it was an accidental self-inflicted wound. The patient (3rd Bengal Cavalry) was wounded on Jan. 27th, 1898, near Khusalgarh, while travelling on escort duty with a sick convoy. He put his left hand over the muzzle of his carbine, not knowing, or forgetting, that it was loaded. The carbine went off accidentally and the bullet passed through his left hand about the middle of the fourth metacarpal, having entered on the palmar surface. Profuse hæmorrhage followed, necessitating the ligature of an artery on his arrival at Khusalgarh. He was transferred by rail to Rawal Pindi next day. The hand was much swollen and inflamed; the wound of entrance was small; the exit wound on the dorsum was ragged and irregular, 1½ in. by 1 in., and involving the fourth metacarpal bone, a portion of which was projecting. The inter-metacarpal space was blackened and sloughy. On Feb. 9th a small piece of the fourth metacarpal bone was discharged in the dressings. On March 10th the exit wound was healed; the scar was depressed. Suppuration continued from the palmar wound and there was more dead bone to be got rid of, though it was not loose yet. On April 10th he was sent on three months' sick leave.

The conclusions drawn from these 52 cases are applicable to the clinical results of these cases only and they must not be considered in the light of generalisations as to the potential destructiveness of this or that projectile. The numbers given are too few for the basis of broad general comparisons, there being only about a dozen cases illustrating the effects of each of these four varieties of bullets, but perhaps these remarks may elicit confirmatory results from those who have had a wider experience.

THE RINDERPEST IN SOUTH AFRICA.

BY JOHN MABERLY, L.R.C.P. LOND., M.R.C.S. ENG.

IN two former communications[1] I endeavoured to place before the readers of THE LANCET as clear an account as possible in a short sketch of the origin and progress of rinderpest in South Africa as well as of the efforts which were being made to overcome its terrible effects, and I shall now try to place on record the work since done and the brilliant victory which has at last been won by scientific research over this the most fatal plague known among those valuable allies of the human race—the horned cattle. In those communications the brilliant discovery of Professor Koch of the antitoxic power of the bile taken from oxen suffering from the disease was recorded, and also his initial work with regard to the use of antitoxic serum procured from animals who had recovered from the disease, which work has since been brought to such a happy and successful conclusion by the labours of Dr. Kolle, who came out to carry on Professor Koch's work, and of Dr. George Turner, the Government Health Officer of Cape Colony. It is very satisfactory to be able to place on record the fact that the name of an English medical man is associated with this, perhaps one of the most important achievements in the antitoxic method of treating disease, since it shows that we are coming into line with the great continental discoveries of this century in the methods of bacteriological research. Professor Koch proved that the serum of cattle which had recovered from an attack of rinderpest, when injected under the skin of healthy cattle, protected them from the poison of rinderpest for a short time. He also proved that a mixture of 99 parts of this serum with one part of rinderpest blood, when injected in a series of doses of 20 c.c. into healthy cattle, gradually increased this immunity to a very great extent; but on discovering the immunising power of bile he abandoned further work on the serum treatment as it appeared too troublesome when it came to be applied to large numbers of cattle and also at that time to be inferior to

[1] THE LANCET, Nov. 13th and 20th, 1897.

Digitized by Google

the bile treatment on account of the impossibility of obtaining sufficient "salted" cattle from which to obtain a supply of serum equal to the demand. The disease was spreading at such an alarming rate that it was imperative that some form of treatment should be applied capable of keeping pace with the spread of the infection. Consequently, although the bile treatment was expensive from the number of cattle required to be sacrificed for its material, it was necessary to continue it for the time being and there is now no doubt that it was instrumental in saving many thousands of head of cattle and at the same time in checking the progress of the disease into uninfected areas to a very considerable extent. As time wore on it was found that cattle which had been rendered immune with bile after periods varying from three to six months lost their resisting power and in many instances succumbed to fresh attacks of the disease.

Whilst this race between the spread of the infection and the attempts, more or less successful, to get ahead of it with bile inoculation was going on, Dr. Kolle and Dr. Turner were persevering in their scientific experiments to bring the serum treatment to perfection. Cattle which had recovered from the disease were gradually collected and a stock of antitoxic serum was in this way secured. From July to the end of October, 1897, antitoxic serum in doses varying from 20 c.c. to 100 c.c. was used for treating herds which had already become infected with rinderpest, it being found that bile (as had been pointed out by Koch at the offstart) was quite useless if the animals treated had already been infected with disease, although they showed no apparent symptoms except a slight rise of temperature, and even animals which became infected any time before six days after the injection of bile were not safe. The serum, if given in sufficient quantity, however, proved capable of overcoming the virulence of the disease provided it was applied within three days after the initial rise of temperature. After that stage it appeared useless even in very large doses. It now slowly became certain that the only permanent immunity was to be found among those cattle which had either recovered from the disease naturally or with the assistance of antitoxic serum and the attention of those engaged in scientific research was turned towards endeavouring to discover some method by which a modified form of the disease could be communicated to healthy cattle, since in this way only did it appear possible that the disease would be finally stamped out. The French *savants* in the Transvaal, Dr. Danysz and Dr. Bordet, first proposed a method of first injecting healthy animals with immunising serum and then keeping them continually exposed to the infection of rinderpest by either occasionally smearing their nostrils with rinderpest blood or keeping them among infected herds. In this way they hoped that the animals would take the diseases as soon as the temporary immunity produced commenced to pass off, but whilst some of the resisting power of the antitoxin was still active enough to modify the disease sufficiently to prevent a fatal result. The results, however, were uncertain and the method was abandoned as too cumbersome for actual application. Dr. Kolle and Dr. Turner tried the experiment of first injecting serum and then rinderpest blood a few days after. This was followed by experiments in which rinderpest blood was first injected followed by antitoxic serum in the course of one or two days, but the results of both these methods were uncertain and they were also open to the objection of requiring heavy doses of serum, and the necessity of catching and casting or otherwise handling the cattle treated at least twice was another drawback in actual practice. They then struck upon the happy idea of simultaneously injecting rinderpest blood and antitoxic serum into the same animal at spots in the body sufficiently apart to prevent the two fluids from mixing together at once. The experiments carried on at the Kimberley station in this method proved eminently satisfactory and it was decided to give the method a thorough trial by placing at Dr. Turner's disposal the cattle living on Robben Island, the Government leper station, situated in Table Bay, which up to this time were entirely free from the disease. The experiments carried on there are so important in their bearing on the future treatment of the disease that it will be well, perhaps, to give them in some detail.

Dr. Turner arrived at Robben Island on Dec. 1st, 1897. The first thing done was to collect all the cattle, and as several of the cows, 29 in all, were heavy with calf Dr. Turner deemed it inadvisable to subject these animals to rinderpest even in a modified form because the fever is liable to cause the cows to miscarry and such miscarriages are frequently fatal. As it would have been manifestly imprudent to introduce rinderpest into the island while some of the cattle were unprotected it was decided to protect these cows in calf by the injection of 150 c.c. of protective serum; this quantity had been found sufficient to immunise for six weeks or more. In this way they would incur no danger of infection when the other animals were infected. This treatment had the further advantage of demonstrating the possibility of producing a temporary immunity amongst dairy cattle without stopping the secretion of milk, a matter of very considerable importance. About five days after the injection of protective serum one of the cows so treated calved in the ordinary course and the calf was born alive and healthy, thus showing that even so large a dose as 150 c.c. of antitoxic serum was not detrimental to life in utero. On Dec. 8th, blood which had been taken from an animal suffering from rinderpest at Kimberley on Dec. 6th was brought to Robben Island and Dr. Turner immediately commenced his work of simultaneous inoculation on the rest of the cattle on the island—in all 52 in number. Each head was injected behind one shoulder with 0·5 c.c. of rinderpest blood and with an average of 25 c.c. of antitoxic serum behind the other shoulder. The dose of antitoxic serum was varied according to the size of the animal, 25 c.c. being considered the proper dose for animals weighing about 600lb. About two days after the inoculation had been performed Dr. Turner received a letter from Dr. Kolle stating that the dose of this sample of serum should have been taken at an average of 30 c.c. instead of 25 c.c. as at first stated; consequently it was decided to give 25 of the animals a second larger dose of serum in order to prevent the possibility of too great a fatality. The rest were allowed to take their chance. Of these 25 cattle 8 showed no signs of fever chiefly owing to the second dose of serum having been too large. Of the remaining 27 which had not received a second dose of serum 4 showed no signs of fever. Out of the whole number treated only 1 died—an old cow in very low condition; 14 of the animals operated on were cows giving milk at the time. The secretion during the height of the fever was diminished but not otherwise altered; in one it was entirely arrested for twenty-four hours but again reappeared. Dr. Turner, in order to test the quality of the fluid, drank a pint of raw milk —taken from a cow suffering from the modified disease— every morning fasting. This did not produce the slightest ill effect upon him and the milk was used in the public institutions just as usual. As a rule, beyond fever nothing indicative of rinderpest could be noticed in the animals. The exceptions were: 4 purged and had discharge from the eyes and nose (one of these passed blood in the fæces); 2 had runnings from the eyes and nose, and 4 did not eat well for a day or two. The fever commenced about the sixth day after the inoculation and lasted on an average four and a half days; the highest temperature reached was 107° F.

A second series of inoculations carried on under similar conditions at the Government farm, Tokai, near Capetown, gave similar results. 39 animals were "simultaneously inoculated"; no deaths occurred, but 29 showed symptoms of the disease. One cow gave birth at full time to a dead calf and another aborted. The 10 which showed no signs of fever were tested ten days after the first inoculation by injections of 10 c.c. of virulent blood, enough to kill 10,000 full grown oxen. The result was that they reacted in just the same way as other salted cattle and in no case were any symptoms visible. This question of the duration of immunity after an apparently unsuccessful simultaneous inoculation was further tested at Kimberley and it was found that the immunity conferred was active for some months and up to the present sufficient time has not elapsed to decide how long this immunity lasts, whether, in fact it is not a permanent one. The success of this method of inoculation having been thus definitely proved it has since superseded the other methods in the treatment of uninfected herds and has been carried out in some instances on a very large scale. In Matabeleland, for instance, 3141 cattle were inoculated in this manner, with the splendid result that only 25 died, something less than 1 per cent.

In order to fully appreciate the importance of this discovery it will be well to take a short review of the history of the disease in other countries previously to this outbreak in Africa. It was estimated towards the end of the last century that rinderpest caused the death of thirty millions of cattle in Germany alone, and in the whole of

Digitized by Google

Europe of two hundred millions of cattle. The most recent extensive outbreak of the disease in England occurred in 1865. According to Mr. John Gamgee, in his "History of the Cattle Plague," it was introduced through a shipload of cattle from Revel on the Gulf of Finland, part of which were landed at Hull on May 29th, 1865, and the rest at London the following week. In a leading article in the *Times* of August 15th, 1865, it was stated that as far back as June 12th animals affected with the Steppes murrain were seen in the metropolitan market. By the beginning of November the plague had been conveyed over the length and breadth of the land. By the end of the year 48,964 cattle were reported as having been attacked; 10,645 only remained alive of this number; the rest had been either killed or had died. This gives an average of recoveries of a little more than 21 per cent. and a fatality of about 79 per cent. The disease continued to spread and to commit great havoc until an Order in Council was issued making it compulsory to slaughter and bury all animals affected with the plague as well as those which had been in contact with them. The beneficial effects of this Order were soon apparent and the disease was finally stamped out. In November, 1866, there were only 8 fresh outbreaks, attacking 16 animals. This outbreak cost the country considerably over £3,000,000 sterling. Another outbreak occurred in July and August of 1872, but it was through the prompt action of the authorities quickly stamped out at a cost of only a few hundred pounds sterling.

These facts help us to realise the enormous value of the work which has now been done in South Africa during the late ravages of the disease. Owing to the vast extent of the country, the comparatively sparse population, and the fact that the buffaloes and several of the many species of antelopes which are found in various districts contracted the disease it was found absolutely impossible to check its progress by the most thorough system of stamping out which could be devised, and in spite of all efforts it gradually spread through the whole country. It is not difficult to imagine what would have been the result if no more effectual means had been devised and, I think, it may fairly be considered that we are well within the mark in stating that under these circumstances we should not to-day have 20 per cent. of the whole cattle of the country alive.

According to the Cape Government statistics published in May, 1898, the total number of cattle in the colony, excluding the Transkei, before the outbreak of rinderpest was 1,639,435. Of these, 575,864 were lost through rinderpest, giving a percentage of a little over 35. The number remaining is 1,063,571 or rather over 64½ per cent. If we now apply the figures worked out in the English outbreak and allow a percentage of recoveries of 20, which is far in excess of what actually occurred in the district of Mafeking before Koch's discovery of the bile treatment—where we find that out of an approximate total of 90,400 cattle 80,000 died, 7800 were shot, and only 2600 remained alive, equivalent to something less than 3 per cent.—we arrive at some idea of the difference in results under the older method and that brought about by the discoveries of Koch, Kolle, and Turner. Instead of 1,063,571 head of cattle remaining we should only have 327,887 head of cattle in the country; which means that a loss of 735,684 head of cattle has been prevented in spite of the disadvantages at which we have been working in having to carry out the scientific researches which led up to this result during the time that the epidemic was raging. If now we estimate the cattle thus saved at the rate of £4 per head we arrive at the conclusion that the steps taken to discover a remedy for the disease have resulted in a saving of £2,942,736, or close on £3,000,000 sterling, so that even if the rinderpest bill comes to something like two millions of money we are still one million to the good. Besides the fact that we now have in our possession a remedy which has brought about the astounding result that the death-rate of the disease has been reduced from one of between 80 and 90 per cent. to the trifling one of something like 2 per cent., it must be borne in mind that the figures given as representing the probable saving brought about by the scientific work done for the disease in South Africa is reckoned at the lowest possible figure, both as regards the probable percentage of cattle which would have been lost and also the value per head. The amount really saved would probably be quite fairly represented at an average of from £5 to £6 per head, and in this case would be nearer five than three millions of money.

The facts brought to light by the scientific research carried on during the outbreak of rinderpest in South Africa of the last two years are of so valuable a nature that this paper would not be complete without giving a summary of the more important of them.

A.—As regards the etiology of the disease neither Koch, Kolle, nor Turner have so far succeeded in satisfying themselves that they have discovered and isolated the specific microbe of rinderpest, and their experience leads them to believe that up to the present it has never been isolated, although various observers claim to have done so, but on very insufficient grounds. They believe, however, that a specific micro-organism does exist and that it is of sufficient size to be visible through the medium of modern lenses for the following reason—viz., that if defibrinated rinderpest blood be filtered through a Pasteur bougie the clear filtered serum may be injected into clean animals without any ill effect, while the corpuscles and fluid which remain in the filter cause the disease. The same thing happens with the still more porous Berkefeldt filter. Evidently the organism is either too large to pass through the pores of the filter, or it is contained in the blood corpuscles which are themselves too large to pass. To test this Kolle and Turner mixed defibrinated rinderpest blood with five times its volume of 0·2 per cent. salt solution; this destroyed the red corpuscles. The mixture was filtered through a Pasteur filter and though the original fluid was virulent the filtered solution failed in all cases to infect animals when inoculated.

B.—An interesting question has been raised as to how gall taken from rinderpest animals acts as a temporary immunising agent; this question also at present has not been satisfactorily answered. The filtered gall was proved not to be capable of giving the disease and also does not protect from the disease, but the matter which remains on the filter, even after being twice washed with normal salt solution, while it does not communicate rinderpest yet protects the animal from the disease.

C.—A series of experiments was instituted by Kolle and Turner to ascertain the amount and kind of action that immunising serum exercised over the rinderpest virus outside the body, in order to gain some idea of how it produced its action when injected as a therapeutic agent into animals suffering from the early manifestations of the disease or as a protective agent against attacks of the disease—in other words, to compare the action of the serum *in vitro* with its action *in corpore*, in the hope of ascertaining by this comparison some idea of its mode of action in the latter case. Mixtures of rinderpest blood and immunising serum were made of the following strengths:—(1) 0·5 per cent. of blood to serum, (2) 1·0 per cent. of blood to serum, (3) 2·0 per cent. of blood to serum, and (4) 10·0 per cent. of blood to serum. These mixtures were kept in each case twenty-four hours in a cool place before being used. In Experiment 1 10 c.c. of the 0·5 mixture were injected into two animals. The result was negative; neither did the animals take rinderpest nor were they rendered immune, both succumbing eventually to an inoculation with rinderpest blood on the eighth day after the first experiment. In Experiment 2 20 c.c. of the 1 per cent. mixture were injected into 18 animals. The result was that 7 had rinderpest and 4 died; 11 of the animals showed no reaction and were subjected to a second inoculation of rinderpest blood only. All of them had rinderpest and 7 died. A considerable difference in the ultimate result, apparently dependent on the time allowed to elapse between the first and second injections, is noticeable in this experiment. Seven of the animals which had showed no reaction were injected for the second time seven days after the operation; only 3 of these died, 4 recovering from the disease. Of the remaining 4 cattle which had been unaffected by the first inoculation, 2 were injected with virulent blood on the eighth day and 2 on the tenth day after the first operation; all 4 died, thus apparently showing that the first injection had some power in fortifying the animals against the injection of rinderpest blood if this was performed within seven days. In Experiment 3 20 c.c. of the 2 per cent. solution were injected into 3 oxen; in Experiment 4 10 c.c. of the 10 per cent. solution were injected into 3 oxen. In both cases all the oxen died from the disease.

These experiments showed that working with ordinary unfortified serum and virulent blood *in vitro* the virus was destroyed when present in small proportion—0·5 per cent. When the proportion was increased to 1 per cent. the virus appeared to be destroyed in about 60 per cent. of the cases, to be impaired in 20 per cent. of the cases, and to be

Digitized by Google

undiminished in 20 per cent. of the cases treated. In higher proportions the virus was undiminished. Working with fortified serum similar results were obtained.

We may conclude, then, that *in vitro* the bactericidal action of the serum obtained from salted animals is small and that the outside limit of its power does not exceed 1 per cent. of its volume of rinderpest blood even after standing twenty-four hours, but that it does exert a modifying influence on the poison is evidenced by the results of the experiments with 0·5 per cent. and 1 per cent. solutions. If now we take results on the other hand of experiments in which immunising serum was injected into animals already infected with the disease, we find that a dose of from 50 to 100 c.c. of immunising serum is sufficient to overcome and counteract the effect of an injection of even from 100 to 200 c.c. of rinderpest blood, provided the former were injected any time within twenty-four hours after the blood inoculation. A comparison of these results shows conclusively that the action of immunising serum on the virus of rinderpest *in vitro* is infinitely less powerful than when applied *in corpore*. In other words, its action on the poison outside the body is very different from its therapeutic power in the living organism; evidently this difference in its action is brought about chiefly through the intervention of the living cells of the animal experimented on. Dr. Kolle and Dr. Turner suggest that the immunising material present in the serum injected is in an inactive modification, that it acts as a stimulus to the cells, probably nervous, and that these cells, again acting upon the injected material, convert it from an inactive into an active modification.

D.—With regard to the preparation of the serum the first serum used was obtained from an animal which had recovered from rinderpest without any treatment, but the serum proved so weak that it was practically useless. The next step was to attempt to increase the power of the serum by injecting into the animal doses not exceeding 100 c.c. of rinderpest blood. This improved the quality of the serum, as proved by the experiments of Dr. Koch. Dr. Kolle and Dr. Turner were led by degrees to increase the doses of virulent blood up to 4000 c.c., and they found that the power of the serum was thereby most decidedly increased. Experience convinced them, however, that animals which had survived a severe attack of the disease are by no means the best suited for purposes of serum preparation, and they now prepare it from healthy animals which have been immunised by the simultaneous method of inoculation and afterwards fortified by successive inoculations of rinderpest blood. The greatest care is requisite in the examination of the blood used for fortifying animals so as to ensure it being free from septic and other organisms and in order to exclude as far as possible the possibility of it containing the germs of other diseases. The animals having been fortified in the way stated they are bled in the usual way and the serum is collected after the clot has formed or by means of a centrifugal machine. The serum has now to be tested so as to gain an approximate knowledge of its strength. This is done by a series of simultaneous inoculations. 10 or 12 healthy animals are taken, their weights ascertained approximately by measurement to be about 600 lb.. Each is then injected with the same quantity of virulent blood and then, say, 3 of these are injected simultaneously with a dose of 15 c.c. of fortified serum, 3 again with 20 c.c., 3 others with 30 c.c., and perhaps 3 others with 40 c.c. The animals are then allowed to stand; food, water, and shelter only are provided; no treatment of any kind is attempted. From the results obtained the strength of the serum is judged. Suppose that some of the animals injected with 15 c.c. die and that the others are severely ill, that those injected with 20 c.c. have a mild attack, that those injected with 30 c.c. do not all suffer, and that none of those injected with 40 c.c. suffer, it would be considered that the dose of that particular batch of serum should be placed at 20 c.c. for animals weighing 600 lb. The serum is then mixed with carbolic acid in the proportion of 0·5 per cent. of the latter and bottled with proper precautions. It has been proved that it retains its strength for at any rate seven months, but for how much longer is uncertain as sufficient time has not elapsed to show.

E.—As regards obtaining rinderpest blood for the simultaneous inoculation process a difficulty arises in transporting it any distance from the fact that it rapidly loses its virulent properties and any preservative added has a similar action. This difficulty is, however, to a great extent overcome by using the blood of living sheep as a means of conveying the poison to a distance. Although the latter animals themselves do not take the disease, still blood drawn from them from three to eight days after an injection of 100 or 200 c.c. of virulent blood fatally infects oxen injected with it, and it has been proved that the strength of the virulent blood can be virtually disregarded in simultaneous inoculations. The hopes entertained at one time of the method of glycerinising bile as advocated by Dr. Edington have proved fallacious.

Cape Town.

ACUTE NECROTIC CELLULITIS OF BOTH ORBITS.

BY W. T. HOLMES SPICER, M.B. CANTAB., F.R.C.S. ENG.,
ASSISTANT SURGEON TO THE ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS, AND OPHTHALMIC SURGEON TO THE METROPOLITAN HOSPITAL;

AND

HAYDOCK WILBE, M.D. DURH., L.R.C.P. LOND.

THE interest of the following case lies in the extreme severity of the local inflammatory process and in the absence of any discoverable cause.

The patient, aged sixteen years, was employed as a bookkeeper in a poultry shop. On Feb. 5th and 6th, 1898, he first had headache of the left side and blocking of the left nostril. Towards the end of the day on the 6th, he had a rigor. There had been toothache on the same side for some days. There had been no injury. Personally he was a healthy youth and had always been so. One of his sisters, however, about a year before had had acute necrosis of the vermiform appendage within two days of the onset of the first abdominal symptoms. There was nothing else to note in the personal or family conditions. On Feb. 8th the swelling of the left eye began, it increased rapidly on the 9th. The patient's temperature was 102° F., and he became delirious. At 10.30 P.M. on the 9th, the following condition was present. On the left side there was intense dusky congestion of the eyelids and the surrounding skin. The orbital contents were much thrust forward; the eyeball itself was fixed and so much proptosed that the stretched lids scarcely covered it; there was perception of light only. There was some offensive discharge from the left nostril. As a fairly definite sense of fluctuation could be obtained above the eyeball an anæsthetic was given and the orbit was opened at its upper and inner part by an incision about 2 in. long. Deep in the orbit behind the globe was a collection of fetid pus containing fragments of necrotic tissue. The incision was enlarged so as to admit the finger and a careful exploration of the orbit was made. The abscess cavity was in contact with the optic nerve as far back as the apex of the orbit; its walls were perfectly smooth and no swelling or displacement of parts could be felt anywhere; a most careful examination with the finger and probe failed to detect any bare bone. About an ounce of pus was evacuated. The cellular tissue of the orbit was quite grey and dead and there was no bleeding from it. The patient had a restless night afterwards; the temperature was maintained and he continued in a condition of muttering delirium, although quite sensible when roused. On the evening of the 10th anti-streptococcic serum was injected, but it had no effect. On the 11th the swelling of the orbit had increased; the edges of the wound were gangrenous, but the upper lid was less tense. The cornea was quite opaque and compressed into a furrow by the dense edge of the lower lid. As there was a decayed painful tooth in the upper jaw of the same side it was thought advisable to thoroughly explore the antrum and nasal cavities. This was done by Mr. Walsham. The carious tooth was removed and the antrum of Highmore was washed out and found to be perfectly normal; the nose was explored and no bare bone could be found except a doubtful point at the root of the middle turbinated bone; the passage to the frontal sinus was normal and the sphenoidal sinus as far as could be ascertained by probing was normal. At the same time the useless eyeball was excised and the orbit was again thoroughly explored. The only thing found was a small surface of bare bone at the upper margin of the orbit. On the 15th there was no improvement to note. Early in the morning his temperature went up to 107° and he had an access of maniacal delirium. Most of the skin of the upper lid was quite dead and much bare bone could be felt in the roof of the orbit. On the 16th the temperature reached 107°

Digitized by Google

three times and he had a slight convulsion of the right side of the face. On the 17th the orbital plate of the frontal bone was bare over its whole extent and some œdema of the right eyelids was first noticed. The question was discussed as to whether anything further could be done in the way of exploring for an abscess above the frontal bone; but as the œdema of the right eyelid and conjunctiva indicated a probable involvement of the other eye by way of the cavernous sinus it was decided to do no more. The patient was seen by Dr. Ferrier on the 22nd but no further action was suggested. On the 24th there was great swelling of the right lids with proptosis, gangrene of the lids, and deep fluctuation in the orbit, and there was panophthalmitis indicated by hypopyon and suppuration in the vitreous. The whole of the lymphatic glands of the right side of the face and neck were swollen and fluctuating. The tissues of the left orbit were shrunken and had sunk down, leaving the bare bone of the roof entirely exposed. On the 26th the patient died. Permission for an examination of the body could not be obtained.

The question of interest in the case is, What was the point and manner of infection? At the first view of the conditions in the orbit it seemed impossible to avoid the conclusion that there had been a wound of the skin or conjunctiva, and the patient's employment in a game shop gave a reasonable support to the view that he had been infected by some dead animal matter. Careful examination failed to reveal any wound and no history of injury could be obtained, but inasmuch as no thorough examination of the conjunctival folds was possible, owing to the tense conditions of the parts, this view of the case could not be entirely set aside. The possibility of the orbital inflammation being of a pyæmic nature secondary to some focus elsewhere in the body was negatived by careful examination. The next possible source of infection was a suppuration in the antrum started by a carious tooth and communicating itself to the orbit. There was no swelling or tenderness of the antrum, but to set the matter at rest the tooth was removed and the antrum was explored.

Taking the other nasal cavities in order the size and position of the sphenoidal sinus made it clearly possible that an empyema in it might find its way into the orbit; if any foul retention had been found it would not have been difficult to break through the thin partition of bone after enucleation of the eye, but a probe introduced into the cavity from the front did not reveal any abnormality. Similarly the naso-frontal passage did not reveal any abnormal condition of the frontal sinus. With regard to all the sinuses it is improbable that a retention of discharge giving rise to an inflammatory process of such intensity in the orbit could exist without revealing itself by external marks in the neighbourhood of the sinus itself.

It is unfortunate that the case could not be cleared up in the only way which was possible, by a post-mortem examination, but there had been such widespread involvement of all the parts in the neighbourhood before the end that it is more than likely that nothing would have been discovered which would have definitely settled the question of cause.

Orbital cellulitis of this degree of severity resulting in acute necrosis of all the contents of both orbits is fortunately not a common occurrence; among the easily accessible records there does not appear to be a similar case. True orbital cellulitis is always a serious disease and always calls for a guarded prognosis; the thinness of the bony partition separating the orbit from the cranial cavity allows a possible extension of the inflammatory process to the meninges in one direction, while in another the blood-flow from the veins of the orbit to the cavernous sinus provides for a possible thrombosis of the sinus and general pyæmic infection of the body. In the Transactions of the Ophthalmological Society of the United Kingdom, vol. vi., one case of orbital cellulitis with recovery was reported by Mr. Critchett; in vol. x. another case with death was reported by Mr. Snell; in vol. xv. five cases of plastic cellulitis of the orbit were brought forward by Mr. Lawson. Of Mr. Lawson's patients three died, one had the eye removed, and one recovered with imperfect sight. In one case only the cellulitis extended to both orbits. In four of the cases Mr. Lawson said his impression was that the cause was septicæmia, but in only one case could the original focus be traced—a previous acute tonsillitis. In the last case, in which both orbits were affected, the patient was suffering from pyæmia before the cellulitis began, the cause of the pyæmia being undetermined. It is unfortunate that in none of Mr. Lawson's cases, so much resembling the present one in many of their characters, was a post-mortem examination made. In the discussion which followed the reading of Mr. Lawson's paper Mr. Hulke and Mr. Tweedy narrated their experiences of orbital cellulitis. The chief point of interest to be drawn from the discussion was the advisability of making very free incisions into the parts involved, a proceeding which was thoroughly carried out in the present case.

CANTWELL'S OPERATION FOR EPISPADIAS.

BY HERBERT W. PAGE, M.A., M.C. CANTAB., F.R.C.S. ENG.,
SURGEON TO ST. MARY'S HOSPITAL.

THE operation of Dr. F. V. Cantwell, of Trenton, U.S.A., by "transplantation of the urethra" for the relief of complete epispadias with infundibuliform opening into the bladder but without extroversion, deserves to be more widely known, and the short record of a case which I have recently cured by it may serve to bring it to the notice of many who had not the opportunity of seeing his original paper in the *Annals of Surgery* of December, 1895. That the operation is either not known or not appreciated as I think it should be is clear from the fact that the most recent book on operative surgery published in this country this year makes no reference to it, and yet the operation is an admirable one alike in its conception and in its practical value for the cure of a most distressing congenital deformity. I have had one case only, but I believe that my friend Mr. Clutton has treated two or three by it with complete success. Dr. Cantwell's paper was illustrated by drawings which cannot be reproduced here, but without entering into moot questions as to the precise cause of epispadias it may be said shortly that the principle of the operation is to dissect up a mucous and submucous flap, composed of the open urethra, from the extremity of the glans backwards as far as possible into the infundibulum, to separate thereupon the corpora cavernosa from each other by blunt dissection, to form a urethral tube out of the aforenamed flap and to secure it in its rightful place beneath the corpora, which are then united together. The infundibuliform opening is closed by prolonging the incisions for the urethral flap so as to surround it, and by suture of the wounded surfaces thus made to bridge over the funnel which leads into the bladder. The result is the creation of a penis modelled on natural lines, with a well-formed urethra on the under side, occupying, that is, its normal relationship to the corpora cavernosa. Furthermore, the effect of the operation is to produce a penis with a natural curve, hanging properly downwards instead of being turned up on the abdominal wall—a penis, in fact, which in the process of growth is calculated to be available for all the possible uses which may be required of it, and which immediately admits of natural micturition. I am indebted to my dresser, Mr. Hughes, for the notes of the case, and both to him and to my house surgeon, Mr. Power, for their intelligent care of the child after operation.

A boy, aged ten years, was first sent to me two years ago by Mr. Havell of Felixstowe, but it was then decided to postpone operation until the parts were somewhat larger, and accordingly he was admitted again on Feb. 22nd, 1898. There was complete epispadias with an infundibuliform opening above the pubes from which urine was continually dribbling. Nevertheless, there was a slight amount of control and the passage of a catheter showed that there was a well-formed bladder. It hurt him too much to attempt to pass the finger. The penis was small and ill developed and was turned upwards so that the glans lay over the mouth of the funnel. When pulled downwards it was seen that the penile portion of the urethra existed as a flat band of bare mucous membrane reaching from the dorsum of the rudimentary glans back to the bladder opening, where it was lost from view. The corpora cavernosa clearly were there, but they occupied the under side of the organ. There was a good scrotum and both testes were to be found in it. An attack of measles delayed operation until May 18th, when as a preliminary step an opening was made in the perineum and a Watson's silver

Digitized by Google

tube inserted in order that after the plastic operation the parts might be kept entirely free from the contact of urine. From this time forth the boy lived night and day in a warm boric bath, a procedure which I do not doubt contributed largely to the success of the operation as well as to his own comfort. The perineal tube answered admirably and he never complained of it. The plastic operation was undertaken on May 20th and presented no difficulties save such as were entailed by formation of the urethra and accurate suturing. The urethral flap having been freed from the corpora cavernosa on which it lay was moulded into a tube upon a catheter, fine catgut being used for the sutures. The corpora cavernosa were separated from each other with singular ease, and their subsequent union, together with the fixation of the new urethra in its rightful place beneath them, was made with finest silk. Finally, the skin along the whole length of the penis and over the infundibuliform opening was sutured with silkworm gut. A soft catheter was then passed by the natural route into the bladder, secured, and left there. Everything went well after the operation, but on May 24th there was so much œdema of the scrotum that I made several punctures in it, the perineal tube was removed, and one or two of the dorsal silkworm stitches were taken out because of obvious tension. The soft catheter was also taken out, cleaned, and re-inserted. More sutures were removed on May 26th and by June 1st the perineal wound was healed. Already the child had gained considerable control over the passage of the urine and emptied his bladder at will through the retained catheter. He was still kept in the bath. By June 8th the retained catheter was discarded and the urine was drawn off twice a day, not with the object of emptying the bladder, but of obviating a tendency to contraction at the meatus. Removal of the boy from the bath for a few hours revealed slight leakage at the infundibulum, and accordingly on June 18th a small plastic operation, which need not be specially described, was undertaken for the closure of the tiny orifice which was alone the cause of it. This was successful, and after a few days longer in the bath the child was recorded on July 1st as being able to retain his urine for seven hours, as passing it naturally, and as being perfectly dry throughout the day. When discharged on July 7th it was noted that he was able to retain his urine all night and the only defect, if so it may be called, in the result of the operation was a slight tendency to contraction of the meatus, for which the daily passage of a catheter was recommended. The latest reports of his condition are in every way favourable and he is now regularly at school.

It may be said that the result of the operation far exceeded our expectations, and while but small experience can be gained from one case only I feel nevertheless that the record of it may be of use in calling the attention of surgeons to an operation of unquestionable value for the treatment and cure of a malformation so grievous and distressing as that of complete epispadias.

SOME MALFORMATIONS MET WITH IN THE POST-MORTEM ROOM.

BY CHARLES POWELL WHITE, M.B. CANTAB., F.R.C.S. ENG.,

DEMONSTRATOR OF PATHOLOGY AT THE YORKSHIRE COLLEGE, LEEDS; FORMERLY PATHOLOGIST TO THE GENERAL HOSPITAL, BIRMINGHAM.

DURING the eighteen months from March, 1897, to September, 1898, when I was pathologist to the General Hospital, Birmingham, I noticed several malformations which are worthy of being placed on record. The number of post-mortem examinations during that period was 394.

MONSTERS.

Anencephalus.—There was one anencephalic monster which presented the usual features.

Sympus.—There was one "siren monster" of the variety sympus dipus. It was a full-term fœtus and the upper part of the body was perfectly well formed. The lower limbs were united as far as the bases of the little toes, the union consisting of skin and subcutaneous tissue. There was no anus and the external genitals were represented by a semicircular tag of skin ⅛ in. in diameter. There were many malformations of the viscera, which will be noticed under their respective headings.

HEART AND BLOOD-VESSELS.

Absence of pericardium.—There was one instance of this very rare anomaly. It was in an adult woman who died from septic peritonitis following on suppurating ovaries. The heart lay in contact with the base of the left lung, the serous membrane passing directly from the base of the heart on to the root of the lung. On lifting up the heart a trace of the division of the pleuro-pericardial cavity into two could be seen in the form of a fold extending from the lower left pulmonary vein to the diaphragm just to the left of the inferior vena cava. This fold projected ⅜ in. into the cavity. The left phrenic nerve passed along the front wall of the cavity behind the sternum in front of the aorta and right auricle, and reached the diaphragm at the same point as the fold above mentioned; it then passed along the upper surface of the diaphragm and entered its substance at the usual place. The heart itself was normal.

Deficiency of inter-ventricular septum.—This was in a male, aged twenty-three years, who died from acute phthisis. The right ventricle was enormously hypertrophied, the left being much smaller than usual. The deficiency was at the upper part of the septum, the aorta appearing to arise equally from both ventricles. The foramen ovale was closed and the aortic and pulmonary valves were normal. There was no stenosis of the pulmonary artery. The ductus arteriosus was patent.

Deficiency of the aortic valve.—In one case the aortic valve consisted of two curtains only, both coronary arteries arising from behind one curtain. Both curtains were the seat of recent infective endocarditis.

Excess in number of curtains of the pulmonary valve.—In one case there were four curtains in the pulmonary valve. The extra curtain was situated anteriorly and to the right and was smaller than the other three, which were equal in size. All the curtains were healthy and well formed.

Malformation of the tricuspid valve.—In one heart the tricuspid valve presented an unusual malformation. In the middle of the posterior curtain there was an aperture ¼ in. in diameter. This aperture was provided with two small curtains to which were attached chordæ tendineæ, which arose from the inter-ventricular septum. The valve was apparently quite competent.

Left superior vena cava.—In the "siren monster" the left innominate vein ended in the coronary sinus of the heart.

Persistence of the left posterior cardinal vein.—In this case, which was associated with malformation and malposition of the left kidney, the left common iliac vein immediately after the junction of the internal and external veins divided into two. The smaller branch pursued the ordinary course and the larger passed under the left common iliac artery and passed upwards on the left side of the spine. At the level of the third lumbar vertebra this latter vein gave off a communicating branch to the inferior vena cava which passed behind the aorta. It then passed into the thorax and continued as the hemiazygos vein, which was very large. At the level of the disc between the third and fourth lumbar vertebræ this vein received a large tributary which, originating in the left phrenic vein, received in its course the left suprarenal, ovarian, and renal veins. There was another renal vein which passed over the left common iliac artery to enter the inferior vena cava at its commencement.

ALIMENTARY SYSTEM.

Duodenal pouches.—In one case (an adult female) the duodenum presented two distinct pouches. One of these was situated at the site of the papilla, the pancreatic and common bile-ducts opening into it; it was ¼ in. deep. The other was just above this on the posterior wall of the duodenum and just below the opening of the accessory duct of the pancreas; it was ⅛ in. deep and would admit the index finger.

Meckel's diverticulum.—This anomaly occurred four times. In each case it was situated between 2 ft. and 3 ft. above the ileo-cæcal valve. The diameter was about 1 in. and the length varied from 1 in. to 2½ in.

Absence of rectum.—Absence of the rectum and anus occurred in the "siren monster," the sigmoid flexure ending at the brim of the pelvis in a blind extremity.

Imperforate anus.—This occurred twice. In one there was no anal invagination and the rectum terminated close to the

Digitized by Google

skin. In the other the rectum terminated at the tip of the coccyx and was separated from the anal invagination by a thin membranous septum.

GENITO-URINARY SYSTEM.

Absence of genito-urinary apparatus. — In the "siren monster" there was no trace of kidneys, ureters, bladder, urethra, or genital glands.

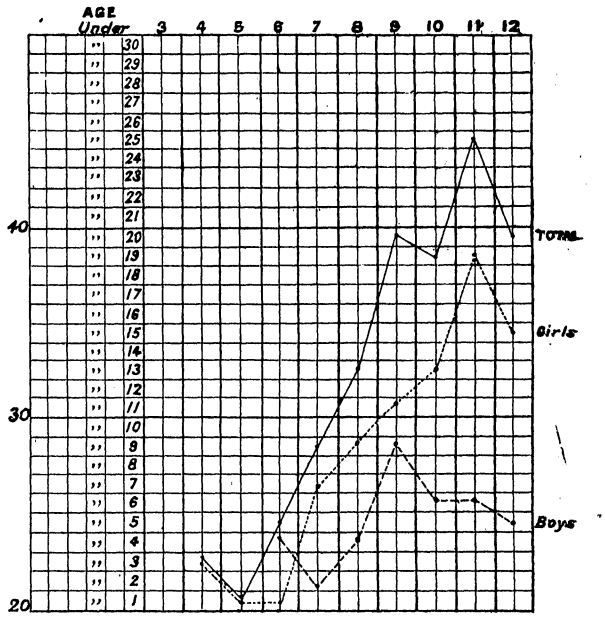
Defective development of one kidney.—In one case the left kidney was represented by a little mass of connective tissue in which the microscope failed to reveal any renal tissue. The renal vessels were represented by a minute artery and vein passing into this tissue. The ureter, which was only pervious for 1 in. at its lower extremity, could be traced upwards as a fibrous cord which was lost in the mass of tissue.

Horseshoe kidney. — Three cases of horseshoe kidney occurred, the union in all consisting of true renal tissue; each had two ureters. The vessels were normal in two of them and abnormal in the third.

Malformation and malposition of kidney.—In a boy, aged seventeen years, who died from phthisis, the left kidney was large, weighing 5 oz.; the hilum was placed anteriorly. It was in the normal position. The right kidney was in the right iliac fossa and was circular in shape. Viewed from the front it had the appearance of two kidneys, one above the other, with their hila adjacent. The pelves of the two halves were distinct and were united by a canal of the size of a ureter which was ½ in. long; the ureter arose from the lower pelvis and passed in front of the lower half. Posteriorly the kidney presented a uniform surface except for a transverse sulcus, in which ran an artery. Each half of the kidney had its own vein, which entered the inferior vena cava. There were two renal arteries arising from the aorta just above the bifurcation; one passed to the front and divided into two, one branch going to each half. The other passed along the sulcus at the back of the kidney and after giving off branches into its substance passed round the outer edge to end in the outer side of the hilum. This kidney weighed 5 oz. The suprarenal body was in the normal situation.

Another case similar to this occurred in a woman, aged forty-four years. It was associated with the persistent cardinal vein above mentioned. The right kidney was normally placed and was normal in size and structure. The left kidney was in the left iliac fossa and resembled the last one almost exactly except that there was one pelvis common to the two halves. One artery arose from the aorta just above the bifurcation and passing to the back of the kidney entered a transverse sulcus in which it passed to the outer edge, round which it turned to end in the outer side of the hilum. Another artery arose from the sacral aorta and passing in front of the left common iliac artery entered the hilum from the front.

Uterus bicornis.—One case of uterus bicornis was recorded. The two horns were ½ in. long. The cervix and the main part of the body of the uterus externally appeared single. There was a septum in the body of the uterus dividing it into two halves. The cervix and the vagina were single.



I am indebted to the honorary staff of the hospital and to Mr. W. E. Bennett for permission to publish these notes.

THE OCCURRENCE OF RHEUMATISM IN CHILDREN SUBSEQUENT TO AN ATTACK OF CHOREA.

BY FREDERICK E. BATTEN, M.D. CANTAB., M.R.C.P. LOND.,
ASSISTANT PHYSICIAN TO THE HOSPITAL FOR SICK CHILDREN, GREAT ORMOND-STREET.

ON the occurrence of rheumatism previously to the onset of chorea numerous tables have been compiled and among the more recent an analysis of 327 cases by Fletcher[1] showing that 26 per cent. of cases suffer from rheumatism previously to the onset of chorea. His figures agree closely with those of S. Mackenzie, who gives 29 per cent., and the majority of observers place the percentage between 25 per cent. and 30 per cent., only Sturges places it as low as 20 per cent., and Sée and Hughes at 48 per cent. and 65 per cent. respectively.

Some time ago, at the suggestion of Dr. Lees that it would be of interest to find out what percentage of choreic children subsequently develop rheumatism, the following analysis was made of cases of chorea discharged from two wards of the Hospital for Sick Children, Great Ormond-street, under the care of the late Dr. Sturges and Dr. Lees during a period of two and a half years—viz., from January, 1892, to June, 1894. During this period 115 cases were discharged from the hospital. Of these 115 cases, in 78 (67·8 per cent.) there was no history of previous rheumatism, while in the remaining 37 (32·2 per cent.) there was some evidence of the patient having previously suffered from rheumatism. The chart shows the age and sex of the children affected.

The abscissæ show the number of children and the ordinates the ages of the same. The dotted line shows cases in girls and the broken line cases in boys.

In July, 1895—i.e., a year after the last patient and more than three years after the first patient had left the hospital—postcards were sent to these 78 cases requesting that they would attend the hospital, or, in some cases where the distance was great, that they would reply to certain questions by postcard. Of these 78 cases, 34 were examined and 23 replied by letter, a total of 57 cases; 19 gave no reply; 2 had died, 1 from scarlet fever and 1 from meningitis. Of these 57 cases there was evidence of rheumatism in 11; in 2 others, although there was no history of rheumatism, nodules were present and well-marked cardiac lesions, and this I consider a definite rheumatic manifestation, although at variance with a statement of Osler in his book on Chorea, p. 16—i.e., 13 cases in all. Of the above 13 cases 2 had attacks of pericarditis with rheumatism and were treated in the hospital, the first after the third attack of chorea and the second six months after the first attack of chorea. Thus 11·3 per cent. of cases without previous rheumatism developed rheumatism within three years.

In July, 1898 (three years later), cards were sent to 44 out of the 57 cases—i.e., to all those who had not had rheumatism up to July, 1895—and from whom a reply had been previously obtained. Of these 44 cases 29 were either seen or heard from. Of these 29 cases 18 had had no rheumatism; 10 had had rheumatism (4 cases were designated as rheumatic fever and 6 cases as rheumatism); and 1 had died from heart disease in the London Hospital. That is to say, there was evidence of rheumatism in 11 of the 29 cases, a further increase of 9·7 per cent., making a total of 20 per cent. within six years. Whipham[2] found that chorea preceded rheumatism in less than 2 per cent. of all cases, while in the present series the percentage amounted within three

[1] St. Bartholomew's Hospital Reports, vol. xxxii., p. 383.

[2] Quoted from Osler: Chorea, p. 15.

Digitized by Google

years of the chorea to 11·3 per cent. and in six years to 20 per cent. In the Report of the Collective Investigation Committee of the British Medical Association on Chorea, 1887, under heading 16, "The Occurrence of Rheumatism during or immediately subsequently to the Attack of Chorea," it is found that 56 out of 439 cases, or 12·7 per cent., suffered from rheumatism during or immediately subsequently to the attack of chorea, but in only 26 of these cases was the attack of rheumatism the first attack—i.e., in a little under 6 per cent. The following table is a summary of the above 115 cases:—

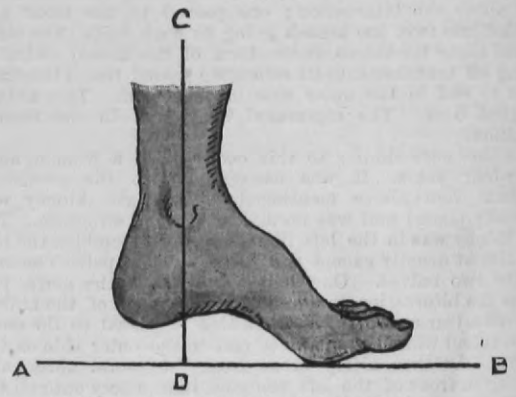
Date.	No rheumatism.		Rheumatism.	
	Number.	Per cent.	Number.	Per cent.
On admission (from January, 1892, to June, 1894) ...	78	67·8	37	32·2
Three years later (July, 1895)	65	56·5	50	43·5
Three years later (July, 1898)	54	47	61	53

Some objections may be lodged against the above figures since in a considerable number of the cases no evidence could be obtained; these cases have been counted with the non-rheumatic and can only tend to lower the percentage of cases in which rheumatism subsequently occurred.

Harley-street, W.

A NEW METHOD OF RESTORING THE ABSENT FUNCTION OF MUSCLES IN INFANTILE PARALYSIS.

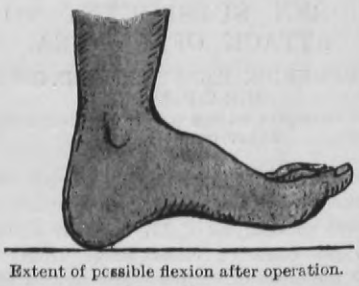
BY NOBLE SMITH, F.R.C.S. EDIN.,
SURGEON TO THE CITY ORTHOPÆDIC HOSPITAL AND SURGEON TO ALL SAINTS' CHILDREN'S HOSPITAL, LONDON.



ALL orthopædic surgeons know that in cases of muscular contraction associated with infantile paralysis—as, for instance, when the calf muscles are contracted and their antagonists, the flexors of the foot, are paralysed—division of the tendons of the contracted muscles is generally followed by improvement in the nutrition of the whole foot. In such a case as I have suggested division of the tendo Achillis not only permits restoration of the foot to a natural position, but it also frequently brings about an increased warmth of the skin and subcutaneous tissue and presumably of the paralysed muscles also. Very little notice has been taken of this improvement in nutrition and when noticed at all the result has generally been attributed to the increased movements of the parts which the release of the contraction has permitted. This explanation does not seem satisfactory for the following reasons. I have found that the almost immediate effect of tenotomy of the tendo Achillis, with as much reduction of the deformity as possible at the time of operation, has set up a distinct increase in warmth of the part the day after operation. This increase in warmth has continued permanently, or at least if it has subsided slightly after a few days yet it has remained distinctly apparent during the period of from two to three weeks or more whilst the foot has been kept absolutely quiescent, and the warmth has continued afterwards as a permanent benefit. Mr. William Adams referred to this subject in his post-graduate lectures published in 1893. He stated that the result "might be due to a certain amount of muscular action taking place in the muscles not contracted, after the tendons of the contracted muscles had been divided." But he remarked that Dr. Brown-Séquard, to whom he mentioned the occurrence, had said that he "believed it to be due to a direct reflex action of the spinal cord, and that a local increase of temperature probably followed all surgical operations, but it would be most observable in cases of paralysis."

We know well that additional warmth, whether produced by external heat or by friction, massage, stimulating liniments, or by any other means, has a beneficial effect upon a paralysed limb, and will help materially in restoring the functions of the paralysed muscles. That is to say, if a muscle is not completely and absolutely paralysed, or perhaps it would be more correct to say that if the nerve-supply of a paralysed muscle or muscles as well as the muscles themselves is capable of improvement, additional warmth of the part will greatly assist in such restoration of power. This being so, it is not surprising that, whatever may be the explanation of the increased warmth following the tenotomy, the result of such increased temperature must act beneficially upon the paralysed parts. Further, it seems probable from the rapid improvement in function of the neighbouring muscles which sometimes occurs that some more direct influence upon the nerves or muscles must take place. After tenotomy of a contracted muscle, in cases in which other muscles have been so far paralysed that they have been beyond the possibility of amelioration, there has yet been a permanent improvement as regards warmth and nutrition. In many instances where the limbs have been cold, blue, and with a tendency to ulceration these symptoms have to a great extent disappeared and almost invariably the skin has lost its blueness.

Operation on the paralysed muscles.—The idea occurred to me that if tenotomy of a sound muscle was capable of producing so much improvement in nutrition in a neighbouring muscle weakened by paralysis, how much more direct an influence would tenotomy of the affected muscle itself have. Acting upon this idea I have operated in this way on two patients whose histories I will now record.



CASE 1.—A girl, aged seven years, was brought to me on Nov. 10th, 1897. Two years and three months previously she had been suddenly attacked by infantile paralysis. There was said to have been complete motor paralysis from the waist downwards, but this began to pass away rapidly, so that in less than a week the patient was able to sit up. The functions of the bowels and bladder were very feeble at first but became normal at the end of five days; sensation was perfect from the first. She had been under the care of Dr. Suckling of Birmingham and had been treated by massage and electricity. At the time of my examination I found the left leg feeble in all its movements, the extensors of the toes (flexors of the ankle) were apparently entirely paralysed, and there was contraction of the calf muscles, so that in walking the heel did not touch the ground. The left leg (measured at the internal malleolus) was ½ in. shorter than the right, and when the foot was flexed as much as the contraction

FIG. 1.

Extent of possible flexion before operation.

FIG. 2.

Extent of possible flexion after operation.

Digitized by Google

would permit there were 1¼ in. between the heel and the ground, as indicated by the line A B at right angles with the vertical axis C D of the leg and on a level with the ball of the great toe, as shown in Fig. 1. The right leg was quite strong, all the muscles acting well. Before operating I requested Dr. Risien Russell to see the patient and he reported as follows: "All the muscles of the left leg respond to Faradaism with the exception of the tibialis anticus and extensor longus digitorum, neither of which muscles respond even to a painful current, and one which when applied to the motor points of these anterior muscles results in marked contraction of the soleus and gastrocnemius on the posterior aspect of the limb. All the muscles which respond to Faradaism also react to galvanism, K.C.C. being greater than A.C.C.; but in the anterior tibial group only an exceedingly feeble response is obtained (A.C.C. greater than K.C.C.) with a very strong current, and one which, applied to the anterior aspect of the limb, evokes marked contraction of the soleus and gastrocnemius. The examination thus shows that there is most pronounced reaction of degeneration in the tibialis anticus and extensor longus digitorum, while the quality of the response from the other muscles of the leg is normal." On Nov. 12th I divided the tendo Achillis of the affected leg; I also divided the tendons of the tibialis anticus, extensor proprius pollicis, and extensor longus digitorum. In the case of the latter muscles, which were considered to be paralysed, there was some difficulty in isolating their tendons. On the 20th I removed the bandage and tried the action of the foot. Upon directing the patient to try to move her foot there was distinct movement of the tendons of the muscles which had previously seemed paralysed. Being so soon after the operation I did not allow more than the slightest effort to be made by the patient. On the 24th Dr. Risien Russell again examined this patient and verified the fact of this restoration of muscular power. The patient made an excellent recovery and has since been walking about with a light temporary support.

One cannot imagine that after two years and three months from the time of the attack of infantile paralysis, seeing that the reaction of degeneration was present, it would

FIG. 3.

Showing the size of the paralysed leg in comparison with that of the sound one.

have been possible, under any ordinary treatment, to obtain restoration of function. Therefore I think we may assume that the operation upon the tendons of the paralysed muscles was the direct means of restoring that power.

CASE 2.—On Nov. 21st, 1895, a girl aged eleven years, was first brought to me. She had suffered from an attack of infantile paralysis at the age of three months and had been subsequently operated upon for contraction of the calf muscles. I was told that during recent years she had got very much worse as regards ability to get about, the left leg being almost useless to her. The left leg was much smaller than the right and deformed, as shown in Fig. 3, and the patient was unable to extend the foot beyond the position there shown. Two years previously to her visit to me she had given up wearing iron supports and the foot had been getting much more deformed. I found there was 2¼ in. shortening of the limb, measuring from the heel to the ground, and the leg below the knee was very cold and blue. The extent of the paralysis was as described below. By means of apparatus she was enabled to walk about with comparative comfort and I only saw her at long intervals. On Oct. 22nd, 1896, I divided a band of the internal lateral ligament which held the foot in the varus position and I was then able to lessen the amount of deformity considerably. On Nov. 3rd, 1897, the patient was walking better, but I found the foot and the lower half of the leg very cold and the circulation very feeble. Ulcers were almost constantly forming and healing up again. As so much benefit in position had been obtained by the cutting of the lateral ligament I thought it worth while to operate

FIG. 4.

Present condition, both feet resting flat on the ground.

on the tendo Achillis and at the same time to divide the tendons of the paralysed muscles. I asked Dr. Althaus to examine the patient first and he reported as follows: "Nov. 3rd, 1897.—1. *N. tibialis.* (*a*) *Faradaism.*—No response on application to the nerve at the back of the knee-joint or to the motor points of the gastrocnemius, soleus, plantaris, flexor digitorum communis, and flexor hallucis longus. (*b*) *Constant current.*—Anodic opening contraction (A.O.C.) absent up to 15 milliampères in the nerve and muscles above mentioned. Kathodic closing contraction (K.C.C.) slightly present between 10 and 15 milliampères. A few voltaic alternatives cause this response to be diminished. 2. *N. peroneus.* (*a*) *Faradaism.*—Fair response with 8 R. A. Stower's induction coil on the nerve, and on the motor points of the peroneus longus and brevis, the extensor digitorum communis, the tibialis anticus, extensor hallucis longus, and the interossei dorsales. (*b*) *Constant current.*—Slight A.O.C. on application to the nerve and the motor points of the muscles, and stronger K.C.C. in the same, with 10 milliampères." In operating I divided the tendo Achillis (muscle acting soundly) and the tendons of the tibialis anticus, extensor proprius pollicis and the extensor longus digitorum (apparently paralysed), and I also broke down some very firm adhesions which prevented the free movement of the tendo Achillis. On Nov. 24th, three weeks after the operation, I found the leg and foot quite warm, the foot

Digitized by Google

in excellent position, and a great improvement in the action of the muscles." Dr. Althaus reported again as follows: "Nov. 24th, 1897.—Farado-muscular response increased in the sphere of the peroneal nerve, especially tibialis anticus, extensor digitorum, and extensor hallucis longus. No other marked change." Her present condition, Oct. 5th, 1898, is as follows (Fig. 4). The patient is now able to walk about with only a very slight limp and suffers no inconvenience. She wears a light apparatus to take the place of the weak anterior muscles and only requires ¼ in. extra thickness on the heel and sole of the left boot. The foot and leg are well nourished and she has never suffered from chilblains or ulcers since the last operation. Dr. Althaus saw her this day and reported that "the leg seems altogether better. Electrically less current strength is required to cause muscular action."

It will, of course, require far more experience than that derived from the above cases to enable us to form a fair estimate of what may be expected from division of the tendons of paralysed muscles. It is obvious that such a procedure cannot be expected to restore action in muscles which have become absolutely degenerated, nor can we expect paralysed nerves to be capable of regaining their function. It seems certain, however, that the significance of what is called the "reaction of degeneration" must be modified, for it would appear that this symptom does not prove that no power of recovery exists. The results in the two cases recorded above are so definite that I cannot see any other explanation of the benefits derived than that suggested. The advantages are obvious and great. In the first case it means the difference between the child being absolutely cured in a few months and having to wear some mechanical support for the rest of her life. In the second case, although some weakness remains, yet the improvement is very considerable, and I would further point out that this improvement is distinctly more than could be expected as the result only of making the joint more free. I could record other cases in which apparently similar results have been obtained, but as no electrical examination was made before operation I prefer to limit my report to the above two instances.

Queen Anne-street, W.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

A RARE, IF NOT UNIQUE, FRACTURE OF THE TIBIA.

BY LEONARD MOLLOY, M.A., M.D. DUB.,
HONORARY SURGEON TO THE VICTORIA HOSPITAL, BLACKPOOL.

THE patient was a man, aged sixty-five years. On May 19th, 1897, while getting into his cart with his right foot on the step his pony started. He endeavoured by hopping along on his left foot to keep pace with the pony and so clamber into the vehicle, but while so doing he fell away from the trap on to his left side. He felt that he had sustained an injury to his left knee and found that he could not stand. He was removed to hospital where he came under my care. The knee-joint was enormously swollen and it was exceedingly difficult to localise the injury, but I came to the conclusion that there was an almost vertical fracture through the head of the tibia, opening, of course, into the joint, and that the greater part of the external tuberosity, with the fibula attached to it, was separated from the head of the bone. There was no fracture of the fibula. The difficulty of diagnosis was increased by the fact that there was shortening of the affected limb to the extent of 1½ in., but this I was enabled to satisfy myself was due to a fracture of the left femur which the patient had sustained in childhood and for which he had been treated in Genoa. The limb was put up on a Lawrence's back splint and so treated throughout. An attempt was made to take a radiogram of the injury before the effusion into the joint had subsided, but it was unsuccessful. Later, however, a radiogram was taken by Mr. T. D. Whittington of this town, of which a reduced reproduction of the photographic print is annexed. The photographic plate was placed behind the knee. From measurements made on the original radiogram it appears that the fracture ran from a point on the articular surface of the head of the bone, 2½ in. from the internal border of the internal tuberosity, almost directly downwards for 2 in., when it came flush with the shaft of the bone and so separated the major portion of the external tuberosity. This fragment could be moved antero-posteriorly, when the resulting crepitus gave one the idea of two broad surfaces rubbing one upon the other. I am quite sure that there was

Radiogram showing deformity of head of tibia resulting from fracture.

no other line of fracture in the head of the bone. Heydenreich's plate of an injury to the "head of the tibia with division of the superior extremity into *many* pieces" shows a **W**-shaped line of fracture, one of the limbs of which takes exactly the line which, I believe, was present in the above case, the cause being, as in this, concussion of the tibial head by the femoral condyles. I am unable to find a record of a similar case to the above. The patient is now able to walk as well as he did before the accident. On measurement with callipers I found that there was broadening of the head of the tibia from side to side to the extent of ¾ in.

Blackpool, Lancs.

SUCKLING A CAUSE OF ABORTION.

BY T. M. CALLENDER, M.B., C.M. EDIN.,
LATE RESIDENT SURGEON ROYAL MATERNITY AND SIMPSON MEMORIAL HOSPITAL, EDINBURGH.

I THINK the following case of abortion of interest on account of the cause which I attributed it to—viz., suckling.

The patient, a woman, aged about thirty years, who had had five children, was well-developed, strong, and healthy, with nothing abnormal in her previous menstrual history. There was no history of endometritis or of specific illness. Her first child was born seven years ago and her last twelve months ago. All her labours were normal except the last but one, when the child was stillborn. It was a breech presentation and there had been some ante-partum hæmorrhage two months before birth. There were no previous miscarriages. Since the last child was born she had one menstrual period, three months ago; she missed the next period and at the date when she should have had her third period she began to suffer from uterine pains and hæmorrhage. She had suffered from morning sickness during the last month. Her breasts were large and full of milk, which was watery in

Digitized by Google

consistence. I was sent for on the third day of the hæmorrhage and found abortion to be inevitable. I packed the vagina with iodoform gauze and gave ergot. A two months' abortion came away entire. In trying to discover the probable cause of the abortion I could find none save the fact that the patient was in the habit of putting her baby to the breasts three or four times daily. On making careful inquiry I found that the pains began while the child was at the breast, and that the next time she put the child to the breast the pains increased in severity and were followed by hæmorrhage. I have no doubt but that in her case the uterine contractions had been set up reflexly through putting the child to the breasts and that the contractions had been sufficiently powerful to bring about the miscarriage. Playfair in his "Midwifery," quoting Tyler Smith, states that suckling as a cause of abortion is not infrequently met with.

Sidcup, Kent.

CONCURRENT ERUPTION OF MEASLES AND CHICKEN-POX.

By H. W. WEBBER, M.D. LOND.

A BOY, aged four and a half years, was seen first on July 12th, 1898; he then presented the appearance typical of commencing measles, rash in moderate amount on the face and behind the ears, with a few scattered spots on the trunk and limbs, coryza, sore-throat, and bronchial catarrh. On July 13th the rash had come out plentifully and cough was troublesome. On July 15th an eruption of papules made its appearance and by the next day these developed into the vesicles characteristic of chicken-pox. Both eruptions ran their normal course, the measles rash fading gradually and ending in a fine desquamation, that of chicken-pox terminating in the usual scabs.

A Mirror OF HOSPITAL PRACTICE, BRITISH AND FOREIGN.

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv. Procœmium.

ROYAL FREE HOSPITAL.

A CASE OF EXTREME DEFORMITY OF THE LOWER EXTREMITIES; OPERATION.

(Under the care of Mr. W. H. BATTLE.)

THE following case well illustrates two points of importance. The first is the very great amount of atrophy and deformity which may occur as the result of general malnutrition in an adolescent; and the second is the marked improvement which in such cases follows multiple osteotomy and attention to the general health. It is difficult to say what, if any, special dyscrasia led to the replacement of so much of the bone by fatty tissues.

A woman, aged twenty-one years, was admitted into the Royal Free Hospital on Nov. 26th, 1895, under the care of Mr. Battle. Until she was sixteen years of age there was nothing wrong with her legs. At that time she was working in a warehouse, where she had to stand about eight hours a day, and her right leg began to be painful and to swell. About a year later she noticed that it was getting out of shape and she left the warehouse and took a place as housemaid, but here also she was much on her feet and her right leg grew worse. She was admitted into the Westminster Hospital and Mr. Davy "took a piece of bone out of the right leg," which had become bowed inwards, and it was put up in plaster. At that time the patient thought the left leg might have been very slightly bowed outwards, but it gave her no trouble. She remained in the Westminster Hospital for three months and when she came out her condition was at first much improved, but about two months after leaving off the plaster the leg began to get painful again. The pain in the right leg compelled her to lean more on the left leg and that soon began to give way. In December, 1894, she had to take to a crutch and gave up work as a housemaid, though she continued to do other work which did not require kneeling. In March, 1895, the pain had become so much worse that she gave up work entirely and since then had done none. The family history was indefinite and unimportant. The patient on admission was fairly healthy in appearance and presented no abnormality beyond the deformity of her legs. Both legs were greatly altered, the right knee was strongly bent inwards towards the left (genu valgum), and the left knee was equally strongly inclined outwards (genu varum). In the right knee the inner condyle of the femur reached a distinctly lower level than the outer condyle and the ligaments were much loosened. The right femur had a marked curve with its convexity forwards. The head and upper 4 in. of the tibia were bent backwards and formed a curve with its concavity forwards with the rest of the bone, which was fairly straight. Just below the concavity were two scars, each about half an inch in length. This was the place from which, according to the patient, a piece of bone was removed at the Westminster Hospital. When lying with the thigh in the natural position and the knee extended the internal malleolus was 9 in. to the right of the middle line. The knee was greatly deformed, its antero-posterior diameter being much greater, and its transverse diameter less, than the corresponding diameters of the opposite side. The left femur was bowed outwards and the left leg was much rotated inwards; the ligaments of the left knee-joint were loosened to some extent, but less than the right. When the patient lay with the knee extended the left external malleolus was 3 in. to the right of the middle line. The patient could stand alone when placed on her feet, though not firmly, but she was unable to walk without a crutch or some other support. On further examination it was evident that some slight amount of movement could be obtained in the upper end of the shaft of the right tibia and Mr. Battle thought that the union after the last operation was probably fibrous. He therefore ordered long outside and back splints in the hope that some of the deformity might thereby be removed; an iron tonic was also given. She had a slight feverish attack on Dec. 24th but soon recovered from it. No obvious improvement having occurred, on Jan. 10th, 1896, Mr. Battle operated on the left leg. An incision about half an inch long was made on the inner side of the left thigh about a finger's breadth above the internal condyle and carried down to the bone and with a chisel the bone was divided; very little force was required for this as the bone was soft and very vascular. The wound being closed with a pad the leg was wrenched into a very good position, the femur being practically straight. A second incision was made about two inches below the tubercle of the tibia over the internal surface of the bone and this bone was divided in a similar manner; it was even softer than the femur and as the chisel was being driven in the medullary fat oozed out of the wound. The tibia was put straight and all deformity removed except a slight inward rotation of the foot. The limb was put up in a plaster-of-Paris splint which extended from the hip to the toes. Very little pain followed the operation. On Jan. 28th Mr. Battle operated on the right leg. An incision 1 in. long was made on the inner side of the right thigh, commencing about 3 in. above the level of the upper border of the patella; it was carried down to the bone and a Macewen's osteotome having been introduced the bone was partly chiselled through and then broken. As the bone was being cut into some oily fluid exuded from the wound. The tibia was then treated similarly through an incision about 2 in. below the lower margin of the patella and a little internal to the middle line at the same place at which the previous osteotomy had been done. The position of the leg still not being satisfactory Mr. Battle decided to divide the fibula and this was done through an incision on the outer surface of the leg about 4 in. below the head of the bone. It was noticed when the bones were being divided that the tibia and fibula were much harder than the femur. The wounds were sutured and dressed and an anterior plaster splint was applied with a long Liston splint on the outer side. The left leg was then examined and considerable external rotation of the foot being found an osteotomy was performed on the tibia in its lower fourth. The left leg was put up in splints in the same way as the right leg. The patient bore the operation well and on Feb. 6th the splints were reapplied. Her

Digitized by Google

general condition steadily improved and early in March the legs were massaged daily; this seemed to improve their nutrition and movement at the knee became free. On April 22nd an apparatus was applied by which some of the weight of the body was conducted by means of iron rods to the legs and feet, thus saving the knees. The right boot had a thick sole in order to equalise the length of the legs. She was soon able to walk, though at first she was easily tired. The patient was seen from time to time and six months after leaving was shown at a clinical meeting of the Medical Society of London, when her legs were seen to be almost straight and she could walk with ease. She had given up the use of the apparatus, as some of the straps were worn and she found it rather cumbersome. Her general health was greatly improved and she looked much stronger.

Remarks by Mr. BATTLE.—The deformity, as shown in the illustration, was very great and disabling, so much so that

Shows a view from the front of the extreme deformity of the lower extremities, the patient standing, as usual, with the aid of her crutch.

the girl could neither stand (except for a short time) nor move without support. It is a little difficult to say how far her pain in standing was due to the strain on the ligaments of the knees and how far it depended on weakness of the limbs. The unusual amount of degeneration of the bones must have been accompanied by corresponding weakness of muscles, whilst her general want of vitality was emphasised by the delayed union in the right tibia. Operation was postponed until the general health had been improved by tonics and good feeding, and when bony union of the tibia had taken place this was regarded as an indication that satisfactory results might be expected after aseptic osteotomy. It is possible that her home surroundings had not been of the best, for at the time of admission there were several superficial sores on the body which soon healed under treatment. She was also at that time somewhat pale-faced and had an anxious expression.

ST. GEORGE'S HOSPITAL.

A CASE OF FRACTURE OF THE TRACHEA AND STERNUM; NECROPSY.

(Under the care of Mr. G. R. TURNER.)

WE have already referred in an annotation[1] to the case reported below, and the fuller details which we publish now confirm the opinion expressed there that as no dyspnœa was present and as the patient survived the injury fourteen days death was probably due to some other condition and not to the rupture of the trachea. Undoubtedly the calcification of the trachea was a great predisposing cause of the lesion, but that the force causing the accident was very great is shown by the extensive injury to the sternum and ribs. It is a point of interest that the backward displacement of the manubrium slowly rectified itself. At least three cases have been recorded of complete rupture of the trachea in which recovery occurred.

An old man, aged seventy-three years, was on Sept. 15th, 1898, admitted into St. George's Hospital. The patient, a night watchman, was resting his chest upon a cross-rail and looking down the shaft of an uncompleted lift, being unaware that the lift had commenced its descent from above. The descending mass came in contact with the back of his head and forcibly flexed his head upon his chest. He was able to walk, but with groans complained of pain in his neck, whereupon an examination was made and the following conditions were found. There was a large hæmatoma over the occipital region without any marked injury to the superficial structures of the scalp, epistaxis was rather free (and subsided early), and there were some bruises over the nose and malar regions. No external marks could be detected on the neck. The sternum was evidently fractured, the manubrium being displaced backwards, and this was associated with fracture of the second and third ribs or their costal cartilages on both sides. There was considerable pain over the præcordia and particularly behind the suprasternal notch; the pain was found to be much aggravated by a full respiratory movement, by slight pressure, or by coughing, the expectoration being accompanied by traces of blood which was at first considered to be of nasal origin, but on examination of the buccal cavity the soft palate to the left of the middle line extending outwards and forwards was found to be lacerated. The pain was unaccompanied by any marked swelling or deformity of the neck; upon palpation of the neck no crepitus was elicited and no emphysema was present. The displacement of the manubrium seemed too slight and the pain caused by the least degree of extension too great to justify forcible extension of the head upon the trunk in order to rectify the displacement; moreover, the likelihood of some deep-seated mischief at the root of the neck militated against such a procedure; no necessity arose for immobilising the head and neck. Very little inconvenience appeared to be caused by this displacement and the condition rectified itself in about nine days. Though the patient had a slight cough and bronchitis and later developed signs of hypostatic congestion of the lungs, gradually sinking to die on the fourteenth day, yet at no time was the respiration much embarrassed and at no time was there any dyspnœa, dysphonia, or dysphagia. The temperature was about 100°F. throughout.

Necropsy.—The post-mortem examination, in addition to corroborating the lesions diagnosed during life, revealed the following conditions: (1) upon removal of the sternum hæmorrhage into the superior mediastinum; (2) transverse fracture of the cartilaginous portion of the trachea through its whole extent about 2¼ in. below the rima glottidis, whereas the membranous portion was not involved and the œsophagus was in no way injured; and (3) fracture of the horizontal plate of the left palate bone. The cartilages of the larynx and trachea were considerably calcified; the fracture of the trachea could be accounted for by forcible compression between the upper border of the sternum and the vertebral column and the fracture of the hard palate by the presence of some such object as a pipe in the patient's mouth at the time of the accident. The surface of the mucous membrane of the trachea over the seat of fracture was continuous but showed evidence of having been slightly injured.

Medical Societies.

PATHOLOGICAL SOCIETY OF LONDON.

Exhibition of Specimens.

A MEETING of this society was held on Nov. 1st, the President, Dr. J. F. PAYNE, being in the chair.

Dr. T. CHURTON (Leeds) exhibited a specimen of Thrombosis of the Hepatic Vein. The patient was a man, twenty-six years of age. He had never been strong, but although enlargement in the epigastric region had been noticed for two years he was able to work till a month before death. He then (July 12th, 1898) received a blow on the right side, after which he gave up work but did not seem ill. On August 4th he was seized with diarrhœa and two days later the abdomen began to swell and the superficial veins became distended. On the 10th several pints of blood-stained ascitic fluid were drawn off, and on the 13th an exploratory incision revealed the nature of the case. At the necropsy, some days later, a cirrhotic liver was found and one of the hepatic veins contained dark-red and recent clot. The portal veins were free from thrombosis. The cirrhosis was chiefly monolobular. There was a good deal of formation of new bile-ducts. Dr. Churton did not think the evidence clear enough to prove that the cirrhosis was due to congenital syphilis. No other cause, however, such as lead, malaria, alcohol, dyspepsia, and auto-intoxication, or acquired syphilis, could be traced.—Dr. LAZARUS-BARLOW also showed a specimen of Thrombosis of the Hepatic Vein associated with Cirrhosis of the Liver, probably syphilitic. The specimen was taken from the body of a boy, aged thirteen years, who during life presented the ordinary signs and symptoms of hepatic cirrhosis—viz., hæmatemesis, ascites, and slight jaundice. The veins over the front of the abdomen were much distended. There was no direct evidence of congenital syphilis; the teeth were normal and there was no interstitial keratitis. His mother had had no miscarriages before his birth (her third pregnancy), but subsequently had four miscarriages. At the necropsy there was found a localised suppurative peritonitis. The liver weighed 2 lb. 10 oz. and its surface was granulated and mottled. On the upper surface posteriorly was a large mass of cicatricial tissue which extended 1½ in. into the depth of the organ and involved the hepatic veins about their termination in the inferior vena cava. Numerous branches of the hepatic vein, both large and small, were blocked by partially adherent and in many places decolourised clot. The cicatricial mass suggested a former gummatous condition and its edges ultimately became lost in the form of trabeculæ of fibrous tissue which entered the main substance of the liver. At the same time the branches of the portal vein served as centres for a fibrous tissue overgrowth throughout the organ. Microscopically the liver, even in its apparently most normal regions, showed the existence of a mixed fibrosis in an extreme degree. The greater part of the fibrosis was of the multilobular variety, but much of the intercellular variety was also present. No gummata were found at all. The spleen, which weighed 16 oz., showed a large radiating and central mass of fibrous tissue.—Dr. MORLEY FLETCHER showed the Viscera from a case of Congenital Syphilis presenting certain unusual features. An infant, aged three weeks, was admitted to the Children's Hospital, Shadwell, on account of the large size of the abdomen. The child died when seven weeks old. There was neither jaundice nor œdema during the course of the illness. The liver was found greatly enlarged, hard, and with a mottled surface on section. The right suprarenal body was adherent to its under surface. Both suprarenals were much enlarged and were hæmorrhagic. The changes in the liver were unusual. There was almost complete absence of liver cells and a great amount of dense fibrosis. The most important feature was a very extensive and diffuse infiltration of the organs by round cells with an obvious reticulum of young connective tissue fibres, closely resembling the condition described by Hutinel and Hudelo as "a diffuse embryonal infiltration." This resembled in some respects the appearance of a small round-celled sarcoma and it was suggested that some of the so-called diffuse primary sarcomata of infants which had been described might possibly be of a similar nature.—The PRESIDENT observed that the histology of congenital syphilitic cirrhosis of the liver was not yet quite fixed and that of Dr. Fletcher's specimen did not follow the usual description. He had described a peculiar liver in an earlier volume of the society's Transactions in which there was an interstitial cellular infiltration with formation of fibrous tissue quite unlike that met with in typical congenital syphilitic cirrhosis.—Dr. MORLEY FLETCHER referred to a case reported by Dr. Gee and Dr. West, in the St. Bartholomew's Hospital Reports, in which there was thrombosis of the hepatic veins in a child seventeen weeks old. In that case the hepatic veins could not be traced into the inferior vena cava, the orifice being closed by a thin membrane.—Dr. H. D. ROLLESTON agreed that thrombosis of the hepatic veins was very rare and was due to very varied causes. In the cases described by Dr. Churton and Dr. Lazarus-Barlow the congenital syphilitic changes appeared to be more marked at the orifices of the hepatic veins causing stenosis first and then thrombosis. In one case he had seen the thrombosis extend in from the inferior vena cava. Osler had described a case of thrombosis from stenosis of the orifice of the hepatic veins. Delépine had described a case in which thrombosis occurred from rupture of a softened cirrhotic nodule into a hepatic vein. Cirrhosis from congenital syphilis was not always intercellular, but might be multilobular. Probably some cases described as diffuse sarcoma of the liver in children were syphilitic cirrhosis. Although congenital syphilitic cirrhosis passed off under treatment it left the liver more likely to develop ordinary cirrhosis later.—Dr. CHURTON, in reply, said that the opening of the hepatic veins into the vena cava in his case could not be found.—Dr. LAZARUS-BARLOW said that in his case there was no modification of the entry of the hepatic veins into the vena cava.

Dr. CURNOW exhibited a Skull which was referred to at the previous meeting in a discussion on a specimen of acromegaly shown by Mr. Shattock. The skull was unusually dense, weighing 2 lb. 10 oz. The sutures were very prominent and the skull was markedly dolichocephalic and prognathous. The ridge of origin of the temporal muscles and the insertion of the masseters were very strongly marked and unlike those of any European skull. The frontal sinuses were very large. There was no enlargement of the pituitary fossa and the skull was not acromegalic. There was a tradition that this was an Australian skull, but this was certainly not the case. He regarded it as a normal skull with strong racial peculiarity and thought it was African, but would not like to be more precise.

Dr. HUGH WALSHAM exhibited microscopic sections of Epithelial Pearls in the Tonsils. He thought that some forms of tonsil calculi might be due to the calcification of these "pearls." Others were due to calcification of tubercle and others were probably the bony masses described by him at a previous meeting.

Dr. ROLLESTON showed a specimen of Idiopathic Hypertrophy of the Œsophagus from a man, aged fifty-nine years, who had not had any dysphagia or other symptoms referable to the digestive tract. This was vouched for by the patient's daughter, who had always shared his meals. Three inches below the cricoid cartilage the circular muscular coat began to hypertrophy and increased in thickness towards the cardiac orifice. The longitudinal muscular coat was practically normal. Around the outside of the œsophagus there were numerous adhesions but not of any density or sufficiently firm to account for the hypertrophy. Microscopically there was no evidence of fibrosis on the hypertrophied circular muscular coat. The lumen of the œsophagus was not dilated or narrowed. The stomach was larger than natural and the pylorus was small. The kidneys were granular, the left ventricle was hypertrophied, and the prostate was hypertrophied. No obstructive cause for the hypertrophy being discovered it was called idiopathic. Spasm of the cardiac orifice naturally suggested itself as a cause, but there was no evidence either of cardio-spasm during life in this patient or that hypertrophy of the œsophagus occurred in cases of cardio-spasm. The hypertrophy of the circular muscular coat of a part of the digestive tract immediately proximal to a gastric orifice closely resembled and suggested analogies with congenital hypertrophy of the pylorus in infants.—Dr. NORMAN DALTON asked if there might not have been a narrowing of the œsophagus at the point where it passed through the diaphragm.—The PRESIDENT pointed out that the patient's age excluded congenital malformation. The

Digitized by Google

limitation to the muscular coat suggested excessive functional activity from some cause. A similar muscular hypertrophy of the stomach for which no cause could be assigned was sometimes met with.

The following card specimens were exhibited:—

Dr. NORMAN DALTON: Dextro-cardia from a boy, aged fifteen years.

Dr. MORLEY FLETCHER: Dilatation of the Left Auricle.

Mr. SHATTOCK: Molluscum Contagiosum in Birds.

CLINICAL SOCIETY OF LONDON.

Exhibition of Cases.

A MEETING of this society was held on Oct. 28th, Mr. LANGTON, President, being in the chair.

Dr. W. S. COLMAN showed a case of Syringomyelia. The patient was a woman, twenty-eight years of age. She had, when a child, never been able to get about like other children, being apt to fall. When seven years old she had painless whitlows and when ten years old her back was noticed to be twisted. She used frequently to burn herself without experiencing any pain. At the present time she was rather stunted and presented the following symptoms: spastic paraplegia with increased reflexes; wasting of the muscles round the shoulder with diminished electric excitability; and wasting of the intrinsic muscles of the right hand with claw-like contraction of the fingers. Sensation to touch was preserved everywhere, but there was loss of sensation to painful sensations over the head, arms, and trunk as low as the umbilicus with the exception of the face, and complete loss of sense of heat and cold as low as the knees. There were also marked lateral curvature of the spine and vertical nystagmus on lateral deviation. Her general health was good.

Mr. JACKSON CLARKE showed a girl, aged three years, suffering from Congenital Subacromial Dislocation of the Shoulder. The humerus was dislocated backwards on to the acromion. The right arm was pronated and movement was limited. There was a history of some difficulty during the labour, but Mr. Clarke thought that the case was one of congenital dislocation and not of traumatic dislocation during birth.

Dr. SIDNEY PHILLIPS showed a boy, aged sixteen years, suffering from Chyluria which had existed for three years. The urine passed after sleep was milky, whether he slept by day or by night. The ordinary urine was clear. The milky urine contained a large quantity of albumin, fat, and granules, which had been described as the "molecular basis of chyle." It was acid and its specific gravity was 1030. The clear urine sometimes contained albumin but at others was perfectly normal. Dr. Phillips was unable to assign a cause. The blood had been examined repeatedly at night but no filariæ had been discovered.

Mr. WATSON CHEYNE showed an example of Repair of the Bridge of the Nose by Rabbit Bone. The patient was a youth who, eight years ago, met with an accident through which he lost large portions of his nasal bones. In January, 1898, Mr. Cheyne raised a flap of skin from the right side of the nose, exposing the periosteum. He then removed the femur from a rabbit, split it into pieces, and simply laid these on the periosteum and replaced the flap. The wound healed without suppuration, and the result as shown to the society was excellent.

Dr. NORMAN DALTON showed a boy, aged fifteen years, suffering from Double Athetosis. There was a history that labour was difficult but not instrumental. The patient walked well until he was three years old. He now presented restless movements of the face, shoulders, and back muscles and there were the typical athetoid movements of the hands when held out. There was rigidity of the lower limbs, particularly marked in the adductors and in the calf muscles, giving rise to some talipes equino-varus. The symptoms were most marked on the right side. There was also some hypertrophy of the muscles of the hand and shoulder.—Dr. J. A. ORMEROD said that he had shown a similar case to the Neurological Society last year. The symptoms in that case were said not to have come on until the boy left school. Both the movements and the spastic condition of the legs were much more marked than in Dr. Dalton's case. The boy had since died, but no post-mortem examination was permitted.

Mr. HERBERT PAGE showed a case of Ankylosis of the Lower Jaw treated by Removal of a Wedge from the Lower Condyle. The patient was a boy, aged nine years, whose jaw was noticed in 1894 to be nearly ankylosed and in 1897 the ankylosis had become complete. Mr. Page had therefore operated with the view of resecting the joint, but finding that the ankylosis was dense and bony he resected instead a wedge-shaped piece of bone from the neck. The boy could now open his mouth widely.

Dr. BERTRAM ABRAHAMS showed a case of Myxœdema in a child, aged seven years. She was unable to walk until five years of age. When six and a half years old she rapidly became fat, her tongue got large, and in twelve weeks she became helpless and unable to feed herself. She was treated with thyroid extract and within 30 days her weight fell from 44 lb. to 33 lb. and she became more active and was able to go to school. The treatment was left off by her parents and the symptoms returned. There was a curious induration of the muscles of the calf probably due to the deposition of mucin.

Mr. A. PEARCE GOULD showed a case of Lupus treated by Thyroid Colloid. The patient was a woman, forty-seven years of age. She had suffered since childhood from tuberculous glands in the neck and in 1879 the glands broke down and lupoid ulceration gradually extended over the face. Afterwards tuberculous disease occurred in the foot, which was amputated, and she had abscesses in various parts. These had all healed before she came under treatment. She then had an ulcer extending right across the face, reaching from the eyelids to the mouth. Mr. Gould's house surgeon, Mr. Mannington, ordered tabloids of thyroid colloid, which were begun in September, 1898, and in three weeks the face had entirely healed over. A single tabloid of the colloid was being still given daily and the scar tissue had become more supple and the ectropion much less marked, and the pain, which was very considerable, had disappeared. Mr. Gould had seen similar but less marked improvement in other cases.—Dr. J. J. PRINGLE confirmed the value of thyroid treatment and considered that the thyroid colloid was better borne than any other preparation. Unfortunately the cases tended to relapse unless the thyroid medication was pursued continuously.—Dr. A. WHITFIELD said he should be inclined to describe the case as one of scrofuloderma rather than as one of lupus vulgaris and he observed that the ulcerative forms of tuberculous skin lesions were more amenable to treatment both by the serum method and by thyroid medication than the pure neoplasm form of lupus vulgaris.

Mr. CHARTERS SYMONDS showed a girl, aged seventeen years, the subject of congenital syphilis, suffering from Gumma of the Tongue. She had previously had gummata in connexion with the ulna and fibula. She had also had syphilitic eye manifestations. It was noteworthy that these gummata developed while the patient was having vigorous mercurial treatment.

Dr. LEONARD GUTHRIE showed a case of Left Hemiplegia associated with Atrophy of the Right Optic Nerve occurring in a woman, twenty-two years of age, who nine days after the birth of a child was seized with convulsions of an ordinary type which were followed by left hemiplegia. She had subsequently had several fits but the paralysis had gradually improved. Three months after the hemiplegia she suddenly found herself unable to see with her left eye and the disc was now in a condition of atrophy. There was mobile spasm of the left arm and leg. The great toe was hyper-extended but the other toe was flexed so that she walked on the knuckles. He thought that the hemiplegia was due to thrombosis of a branch of the Sylvian artery and that the optic atrophy might be the result of retro-ocular neuritis, both probably the result of syphilis.—Dr. R. D. BATTEN said that he had examined the case and thought the cause of the atrophy was uncertain. He thought that embolism and thrombosis of the central artery could be excluded and from the condition of the fields he did not think that retro-ocular neuritis could account for the atrophy.

Mr. CUTHBERT WALLACE showed a case of Bending of the Neck of the Femur in a child, aged three years. The foot was markedly everted. Movements of flexion were free if the foot was everted, but very restricted if the foot was inverted.

Mr. F. C. ABBOTT showed a child, aged five years, suffering from an exactly similar condition. The child had been

Digitized by Google

unable to walk until the year before and had crawled about on the buttocks. This he suggested had caused the bending, which was in the antero-posterior direction and was not merely a diminution in the obliquity of the neck.—Mr. JACKSON CLARKE pointed out that it was easy to flex the leg up against the body with the feet together and this was the natural position of repose. That, moreover, was the position in which children with congenital dislocation of the hip were often born. He observed that owing to the frequent confusion of coxa vara and congenital dislocation of the hip the statistics previously to the introduction of skiagraphy were absolutely unreliable.

LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY.

Cæsarean Section.—Sarcoma Uteri.—Exhibition of Cases and Specimens.

A MEETING of this society was held on Oct. 21st, the Vice-President, Mr. C. J. WRIGHT, being in the chair.

Dr. BRAITHWAITE read a paper on Two Cases of Cæsarean Section. In both cases Cæsarean section was performed at or about full term of pregnancy in consequence of the pelvis being blocked by ovarian tumours. In neither case could the tumour be got at for removal when the abdomen was opened. Case 1.—The uterus, on exposure, was seen to be of an unusual dark blue colour in consequence of the placenta being attached to its anterior wall. The placenta was divided at the same time as the incision was made through the anterior wall of the uterus. The child was rapidly removed and the uterus was wrapped up in a large hot sponge, which was pressed firmly upon it and at the same time it was lifted out through the abdominal wound. The placenta and membranes were removed immediately after the child. The mother did well and the child is still living and is now over a year old. Case 2.—This was almost precisely similar to Case 1. The mother did well but the child unfortunately died within 24 hours. The following amongst other points were noteworthy in these cases. First, in opening the uterus, especially if the placenta was attached anteriorly, rapidity was of vital importance. The incision should be begun by a scalpel but was better finished by very strong sharp scissors. Secondly, the edges of the incision must be seized and everted and compressed where necessary by a second assistant, not by the one standing opposite to the operator. The hæmorrhage from the divided uterine wall was very easily arrested in this way, as it was entirely venous and at very low pressure. It, moreover, did not come from the whole surface of the wound, but only from two or three points. Thirdly, after the uterus had been emptied of the child, placenta, and membrane, and brought out of the abdominal wound and wrapped in and pressed by a large, flat, hot sponge, the first stitch should, as recommended by Dr. Murdoch Cameron, be put in the middle so as to produce accurate adaptation. Before the wound was finally closed by the last two stitches, which should be at the upper end of the wound, the nozzle of a syringe should be inserted into the uterus and its cavity washed out by hot boric lotion in order to ensure the absence of clot. Fourthly, as it was ultimately absorbed, the best material for the sutures in the uterine wall was green chromic catgut soaked for half an hour in perchloride solution, 1 in 1000. In making the first half of each knot the end should be put through the loop twice instead of once. A knot so made in catgut would hold, otherwise it was not safe if any strain was put upon it, as by vomiting. The sutures should be put in two to the inch, and so deep as just to miss the inner surface of the uterus. If placed at longer intervals, as recommended by Saenger, the wound was not quite safely closed.—Dr. BELL, in an experience of 8000 midwifery cases, had only met with one case requiring Cæsarean section and this occurred lately in a dwarf 3ft. 5in. high whose pelvic antero-posterior diameter was only 1½ in. The case occurred in a poor house and a hurried operation was necessary without recourse to any thorough aseptic arrangements; nevertheless, complete recovery took place both of the mother and child.—Dr. HELLIER deplored the frequency with which children were born with spastic paraplegia occurring immediately afterwards and attributed this to the children being dragged through the contracted pelvis by means of forceps. He advocated in these cases a more frequent adoption of symphysiotomy, which experience had shown was a very safe operation.—Mr. C. J. WRIGHT referred to three cases of Cæsarean section at which he had assisted for deformed pelvis some years ago and contrasted the past with the present successful mode of operating. The respective merits of Porro's operation and Cæsarean section were also mentioned. The existence of ovarian growths in both of Dr. Braithwaite's cases emphasised the necessity for early removal when these were detected in all cases of pregnancy.

Mr. CROFT related a case of Hysterectomy for Sarcoma Uteri following Hydatidiform Mole and showed the uterus removed and microscopic sections of the growth. The patient, aged thirty-two years, had had three children and had been ailing since the birth of the last child, two years previously. After suckling the child for eighteen months the menses returned once or twice and there was then severe flooding. A large hydatidiform mole was removed. About six weeks afterwards intermittent bleedings and offensive discharge with septicæmia having occurred the uterus was explored and the presence of malignant growth was discovered. The septicæmia and general symptoms having been relieved, vaginal hysterectomy was performed. Meanwhile the growth had been examined and reported upon by Mr. Targett of the Clinical Research Association. The tissue consisted of uterine muscle substance infiltrated with sarcoma. The cells were spindle-shaped, and many of them were very large, like giant cells, but the characters did not resemble those of deciduoma malignum. The interest of the case turned on the clinical resemblance to this latter disease and the fact of the malignant growth following a few weeks after the hydatidiform mole. The patient recovered and is so far well, the operation having been performed three months ago.

Dr. CHURTON showed a Large Cirrhotic Liver with Thrombosis of the Hepatic Veins from a man aged twenty-six years. He had been perfectly temperate and no ordinary cause for the disease could be discovered. There was, however, much reason to regard it as a case of congenital syphilis with manifestations long deferred. Keratitis due to this taint is said to appear occasionally as late as the thirtieth or fortieth year (J. Hutchinson).

Mr. LITTLEWOOD showed the following: 1. Bullet-wound of the Knee-joint. The patient was a boy, aged thirteen years, from whose right knee a bullet had been removed on Sept. 28th, 1898. The bullet had lodged just beneath the articular cartilage of the inner condyle. The bullet and skiagram were shown. 2. Sarcoma of the lower end of the Femur. The patient was a male, aged twenty-three years, who had had an amputation through the left thigh just below the lesser trochanter for a huge breaking-down sarcoma of the lower end of the femur. Operation was performed twelve days previously under nitrous oxide and oxygen. The patient was very ill at the time of the operation, having a temperature of 103° F. He suffered remarkably little from shock and has made a very rapid recovery. The specimen was shown. 3. Solid Ovarian Tumour, weighing 17 lb., having many adhesions, removed from a girl, aged fifteen years, on August 8th, 1898. The patient made a good recovery. 4. Double Pyosalpinx and Suppurating Ovarian Cyst (left) removed from an unmarried woman, aged twenty-five years, on Oct. 10th, 1898. Each tube contained 6 oz. of pus and the cyst 12 oz. The patient is making a good recovery. 5. Hat-pin, measuring 4 in., removed from the urethra of a man, aged fifty-four years. 6. Hydatids involving a Portion of Rib removed from a woman suffering from hydatid disease of the chest.

Dr. WARDROP GRIFFITH showed: 1. A case of Post-Diphtheritic Paralysis in a lad, aged nine years. The symptoms came on about a week after a severe sore-throat, the nature of which was not diagnosed. The patient was rapidly recovering, and at one stage his gait had strongly resembled that of pseudo-hypertrophic paralysis. 2. The blood from 2 cases of Leucocythæmia of the Spleno-medullary type. In one case the number of white cells was about equal to that of red, and the number of large eosinophile cells was very great.

Dr. ALLAN: (1) Elephantiasis of the Leg; and (2) Syphilitic Liver.

Dr. TREVELYAN: Miliary Tuberculosis of the Spinal Meninges.

Mr. W. H. BROWN: (1) Hand with Seven Fingers; (2) Sarcoma of the Neck after Injection with Coley's Fluid; (3)

Digitized by Google

Skin Grafting after Severe Burns; and (4) Malignant Disease of the Prostate.

Dr. CHURTON: Cancer of the Liver, with Microscopic Specimens.

Mr. LAWFORD KNAGGS: The Parts removed in a Porro's Operation. (The patient was shown).

Mr. E. SOLLY: Specimen of Complete Inversion of the Uterus.

Dr. HELLIER: Carcinoma Corporis Uteri removed by Vaginal Hysterectomy.

Mr. SECKER WALKER: Case of almost Complete Anterior Staphyloma of both Eyes. Iridectomy was performed in one eye with useful result.

INCORPORATED SOCIETY OF MEDICAL OFFICERS OF HEALTH (Metropolitan Branch).—A meeting of this society was held at 197, High Holborn on Oct. 28th, when Dr. J. F. J. Sykes delivered his presidential address on Some Points in Public Health Administration. Referring to the power of entry possessed by sanitary authorities under the Public Health (London) Act he regretted that no power was given to enter unless a nuisance was believed to exist; this was particularly to be regretted in the case of schools. With regard to drainage regulations he asked for pressure to be brought on the London County Council to issue their long-promised by-laws, and also for an interpretation of the words "making of a drain" and "new drain," as used in the Metropolitan Local Management and other Acts. He also advocated power being given to local authorities to make by-laws for the proper drainage and paving of stables. Speaking on the storage and removal of manure he suggested that as the nuisance from peat and some other kinds of litter arose from its disturbance and transference from one receptacle to another rather than by the transit of the removing receptacle the County Council should provide for the removal to be made in the same receptacle as the storage, by which means disturbance would be obviated and nuisances avoided. Continuing Dr. Sykes said that under the provisions of Section 41 (2) of the London Building Act, 1894, the open spaces to be provided to buildings might be entirely covered in so far as buildings existing in London streets prior to 1895 were concerned; in other words, no open space need be provided to the lowest floors—viz., the basement and the ground floors and possibly an entresol of a house. In consequence of this houses were being built so as not to have even a shaft for the purpose of allowing the drainage to discharge into the open, so that the by-laws of the sanitary authority and the county council, devised with a view to excluding drainage from buildings, especially domestic buildings, were rendered useless by the law of the Building Act, which permitted a building to embrace the whole of its drainage within its external walls. Some remedy was obviously necessary for this growing evil. He further urged that provision should be made for taking samples of polluted or infected foods and suggested the desirability of veterinarians being employed as food inspectors. Other points mentioned included overcrowding (for which Dr. Sykes said a definition was required), the notification by school teachers of absences caused by infectious diseases, and the desirability of making vermin of the clothing, person, or place a nuisance under the Public Health Act.

BECKENHAM AND PENGE MEDICAL SOCIETY.—Consequent on resolutions of two special general meetings this society formally entered on Oct. 28th into affiliation with the Corporate and Medical Reform Association, Limited, the object being to unite these otherwise distinct and independent associations the better to effect their common objects—corporate and medical reform. After a resolution moved from the chair, seconded by Mr. Barton, and carried *nem. con.*, to support the Corporate and Medical Reform Association and to coöperate in its policy and measures, the resolution to enter into affiliation was moved by Mr. Primrose Wells, seconded by Dr. Corbin, and adopted. At the meeting, held at the residence of Mr. Primrose Wells (honorary secretary), Mr. Sturges (President of the society) being in the chair, a deputation consisting of Dr. Lorimer Hart (Sydenham) and Mr. R. B. Anderson attended on behalf of the Corporate and Medical Reform Association and in summing up the question, before putting the motion to affiliate, Mr. Sturges said that he believed this method of affiliating distinct and otherwise entirely independent associations for the great purpose of corporate and medical reform was an entirely new departure in the profession and would obviate much of the inconvenience and dissatisfaction caused by the inertness of large and unwieldy bodies such as one they had in mind; that the policy placed before them by the deputation appeared reasonable and practicable and to be calculated to supply the want of some means of common action, and to supplement that local organisation which, though in that society absolutely unanimous, had failed to protect them and to establish their just claims in face of the inevitable outsider; and he predicted for this new policy and these new methods a great and remarkable success.—It was agreed that the resolution to affiliate should not take effect until and unless ratified by another meeting, which was held on Oct. 21st, and at which the resolution was again brought forward and formally passed unanimously.

THE DERMATOLOGICAL SOCIETY OF GREAT BRITAIN AND IRELAND.—An ordinary meeting of this society was held at 20, Hanover-square, W., on Oct. 26th, the President, Dr. Radcliffe Crocker, being in the chair. The following cases were shown:—The President: 1. A case of Tuberculated Leprosy in a middle-aged Hindoo. The skin affection had existed for ten years. He had been totally blind since Christmas. 2. A case of Urticaria Pigmentosa in a boy.—Dr. T. D. Savill showed two cases: (1) Scleroderma of the Extremities in a woman; and (2) a Case for Diagnosis.—Dr. Alfred Eddowes showed: 1. Alopecia Areata with Leucodermia symmetrically situated on the Inner Aspect of both Knees, the patient being a boy about fourteen years of age. 2. A man recovering from Hodgkin's Disease. There was extensive alopecia areata. Dr. Eddowes pointed out the marked anæmia of the affected areas in this case and in his previous case. Both patients wore wigs. 3. A man with (?) Iodide Rash. 4. A woman with Chronic Symmetrical Œdematous Erythema of the Face, with a Lichenous Eruption affecting both Arms and the Neck.—The cases were discussed by the President, Mr. Buxton Shillitoe, Dr. Phillips-Conn, Dr. Hall, and Dr. Eddowes.

BOURNEMOUTH MEDICAL SOCIETY.—The annual meeting of this society was held on Oct. 26th at the Royal Exeter Hotel, Mr. T. Frederick Gardner, the retiring Vice-President and President-elect, being in the chair.—The honorary secretary read the minutes of the last annual meeting.—The reports of the committee and honorary librarian and the treasurer's audited accounts having been previously circulated among the members of the society were taken as read.—A ballot took place for the committee.—The following are the officers for the year 1898-99:—President: Mr. T. Frederick Gardner. Vice-President: Mr. Bernard Scott. Honorary Treasurer: Mr. A. Heygate Vernon. Honorary Librarian: Dr. W. H. L. Marriner. Honorary Secretary: Mr. D. M. Ross. Committee: Mr. S. L. Clift, Mr. A. C. Coles, Dr. W. H. L. Marriner, Dr. W. Hooper Masters, and Mr. F. Winson Ramsay.—The members and some friends afterwards dined together in the hotel.

GLASGOW OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.—At a meeting of this society held on Oct. 26th the following office-bearers were appointed for the session 1898-99:—Honorary President: Dr. James Stirton. President: Mr. Alex. Miller. Senior Vice-President: Dr. Lawrence Oliphant. Junior Vice-President: Dr. J. K. Kelly. Treasurer: Dr. J. Lindsay. Secretary: Dr. R. Jardine. Reporting Secretary: Dr. Munro Kerr. Pathologist: Dr. Balfour Marshall. Councillors: Dr. A. Richmond, Dr. Edgar, Dr. G. W. Thomson, Dr. Elizabeth Pace, Dr. Marion Gilchrist, and Dr. E. A. Gibson.

THE PLAGUE IN INDIA.—The *Times of India* of Oct. 15th says that Lord Sandhurst was very busy during his late visit to Simla. More than one conference of high officials met regarding the plague question in Bombay and the subject of the provincial and financial status was carefully considered by his Excellency with Sir James Westland. As already announced, the Secretary of State for India has sanctioned the appointment of a special commission to make investigation of a scientific character in India in connexion with plague. The main questions with which the commission will deal are the origins of the different outbreaks of plague, the manner in which the disease is communicated, and the effects of curative serum and preventive inoculation.

Reviews and Notices of Books.

The Nervous System and its Diseases. By CHARLES K. MILLS, M.D. Philadelphia. Edinburgh and London: Young J. Pentland. 1898. Pp. 1056.

ANYONE who has read the contributions to neurological literature which have from time to time come from the pen of Dr. C. K. Mills must take up the present volume with considerable expectations. It may be said at once that these expectations are not likely to be disappointed and that the book, so far as it goes, is worthy of the high reputation of its author. We have said "so far as it goes," and it is well to state at the outset that this volume, after a general anatomical, physiological, and symptomatological introduction, deals only with diseases of the brain, cerebellum, medulla, and cranial nerves. Yet the book is complete in itself and is furnished with an excellent index and a most complete bibliography.

The first chapter is one of 124 pages, comprising a general sketch of the nervous system, a description of nervous tissues, an account of the development of the nervous system, and a section on nomenclature and terminology, advocating a somewhat radical and, in many cases, we believe, unnecessary change in the current terminology. We venture to think that the substitution, e.g., of "callosum" for "corpus callosum," of "dura" for "dura mater," of "thalamus" for "optic thalamus," of "medifrontal" for "middle frontal," and such like, are scarcely changes which will to most recommend themselves as improvements. Yet the attempt to attain to uniformity in nomenclature is one with which most students of neurology will probably sympathise. The general anatomy of the nervous system is dealt with in the next section and all the latest views are incorporated in this description. In the part dealing with the anatomy of the spinal cord no serious attempt is made to describe the destiny of the various tracts. The membranes, blood-vessels, and lymphatics of the nervous system are next dealt with, and following this the architecture and general physiology and the chemistry of the nervous system. Such is the first chapter, and it will not be wondered at that it comprises 124 pages which are abundantly and, on the whole, excellently illustrated.

The second chapter deals with the general pathology and etiology of nervous disease: its symptomatology, the methods of investigation, electrical examination, and electrical treatment. The general therapeutics of nervous diseases are also considered, including diet, climate, baths, and the various forms of special treatment, such as the Weir-Mitchell treatment, hypnotism, and serum treatment.

In the third chapter consideration of the spinal diseases is first entered upon and diseases of the membranes, sinuses, and veins of the brain and also encephalic malformations are dealt with. The account of these is satisfactory, although little new light is thrown upon their origin or symptomatology.

The fourth chapter seems at first sight a digression, but it really is not so, consisting as it does of an account of the histology and physiology of the brain in relation to its focal diseases, so that it includes an account of its minute anatomy, of cortical localisation, of the functions and morbid conditions of the basal ganglia, and of the cerebellum. Cranio-cerebral topography is also dealt with and the modes of examining the brain post mortem, especially with reference to the localisation of lesions.

The fifth chapter is devoted to an account of the diseases of cerebral vessels and of the vascular disturbances of the brain, and is naturally prefaced by an account of the encephalic circulation. It comprises, of course, a clinical description of various conditions, such as cerebral hæmorrhage, vascular occlusion from embolism and thrombosis, intracranial aneurysm, brain tumours, and abscess.

In the next chapter an account is given of the remaining cerebral diseases, including degenerations, the cerebral palsies of children, aphasia, and other defects of speech. This is an extremely satisfactory chapter. The next one is devoted to diseased conditions of the special senses and their related cerebral representations and this is succeeded by a chapter dealing with disturbance of ocular movements resulting from lesions of nerves, nuclei, or cerebral structure. The remaining two chapters discuss morbid conditions of the other cranial nerves—i.e., trigeminal, facial, glosso-pharyngeal, pneumogastric, spinal accessory, and hypoglossal—and diseased conditions of the medulla oblongata.

From the foregoing account the scope and completeness of the book will be evident, and it need only be said that it is very copiously illustrated, that on every page of it the author's intimate acquaintance with the latest neurological literature is evident, and that everywhere it is illuminated by the clinical experience of a highly-trained and keenly observant physician. We congratulate Dr. Mills on the first instalment of his book and we trust that he will be encouraged to complete a work which will, we believe, take a place in the best medical literature of America. As regards printing and typography and character of the illustrations the book is admirable.

The Meteorology of Egypt and its Influence on Disease. By H. E. LEIGH CANNEY, M.D. Lond. London: Baillière, Tindall, and Cox. 1897.

THIS work contains the most complete account of the meteorology of Egypt which we have yet seen. It includes the results of a series of observations undertaken during the three years 1893–96 by Dr. Canney and others at the following stations: Cairo, Helouan, Mena House, Luxor, Assouan, Luxor Fields, and at several points in the Luxor desert. All the observations (except those of the subsidiary stations near Luxor) were taken on the flat brown cement roofs of hotels from 40 to 50 ft. high. The following gentlemen coöperated with Dr. Canney in this work: Mr. Longmore and Dr. Jalland at Assouan, Dr. Bentley and Mr. J. L. Hichens at Mena House, Dr. Kauffmann at Cairo, M. F. Douat at Helouan, and Dr. Page May. The general result of Dr. Canney's observations is to bring out the superior climatic advantages of Upper, as compared with Lower, Egypt. Thus for the four months December to March Luxor has a mean temperature 3·3° warmer than Helouan, and Assouan 7·8° warmer than Helouan. Again, the fall of mean temperature in January, which is 4·5° at Mena House and 3·5° at Helouan, is 2·7° at Luxor and only 1·8° at Assouan. The mean daily variation of temperature is naturally greater in Upper than in Lower Egypt. For the four months included in the observations it was found to be 21·7° at Mena House, 22 3° at Helouan, 28·4° at Luxor, and 27·6° at Assouan. "With regard to the fall of temperature at sunset," says Dr. Canney, "much has been said by nearly everyone who has ever travelled in Egypt, and it has often been described as very great. So far as these continuous observations show, the fall of temperature from 4 P.M. to 6 P.M. (including the hour of sunset) is only 1° more than that for the following two hours to 8 P.M. in Lower Egypt, whilst in Upper Egypt the fall from 4 P.M. to 6 P.M. is only 2° more than that for the following two hours. In the desert the reduction of temperature from the maximum to the minimum is gradual, though rather more rapid up to 6 P.M. than after that hour." The relative humidity is decidedly less in Upper than in Lower Egypt. Dr. Canney gives the mean for two years as 54·2° at Helouan and 40·5° at Assouan. The

Digitized by Google

absolute humidity (grains in 10 cubic feet of air) is stated to be 35 at Mena House, 30 at Helouan, 31 at Luxor, and 28 at Assouan. It is characteristic of Egypt that in these observations "rain was not recorded." Rain falls at Cairo on an average about ten to fifteen days in the year, the total precipitation being less than half an inch; Upper Egypt is practically rainless. It need hardly be said that the climatic differences between Upper and Lower Egypt are modified to an important extent by the influence of the cultivated Delta upon the latter. This influence, so far as it goes, detracts from the pure "desert" quality of the air at Cairo, Mena House, and Helouan.

Dr. Canney strongly advocates Egypt (and especially Upper Egypt) as a resort in the following cases: phthisis (non-erethic cases, hæmorrhagic cases, chronic quiescent cases, and cases associated with bronchitis), asthma, chronic bronchitis and emphysema, impaired convalescence from pneumonia and pleurisy, chronic nasal and pharyngeal catarrh, mental overstrain, insomnia, Bright's disease, rheumatism and gout, dyspepsia, sciatica, &c. This is a long list which we have not space to discuss. The best air for phthisis (speaking generally) is mountain air. The next best is desert air. While Dr. Canney's book contains a great mass of really valuable information it is open to criticism in some particulars. It is badly arranged and the various tabular statements are not sufficiently self-explanatory. Some of the remarks regarding the influence of cultivated land upon climate seem to us erroneous. The mean daily variation of temperature is given as 25° at Cairo and 8° at Alexandria. This latter figure is certainly too low. The following sentence is hardly a model of philosophic impartiality and caution: "It will be observed that the cases deriving the greatest benefit from the climate of Egypt are mostly diseases unknown or rare in Egypt—phthisis, asthma, bronchitis, gout, Bright's disease, insomnia, rheumatoid arthritis, dyspepsia, and sciatica. In all these cases the relief to be obtained is very great in Egypt, and at the same time *they are cases for which little or nothing can be done in Europe*, with the exception of phthisis which has possible alternative resorts." The italics are ours.

Perityphlitis and its Varieties: their Pathology, Clinical Manifestations, and Treatment. By FREDERICK TREVES, F.R.C.S. Eng., Surgeon to the London Hospital, &c. (Reprinted from "A System of Medicine," edited by T. Clifford Allbutt, M.D. Cantab., F.R.S.) London: Macmillan and Co. 1897. Pp. 61. Price 2*s.* 6*d.*

THE high character of the individual contributions to Clifford Allbutt's "System of Medicine" fully justifies the reappearance separately of some of the more important papers. Mr. Treves's article on "Perityphlitis" is especially suitable for publication in this isolated form, for the subject is very well defined and the frequency of the occurrence of this disease makes it of especial interest.

The author prefers the name Perityphlitis to Appendicitis, and we heartily agree with him that the latter is uncouth, but there seems little doubt that it will ultimately prevail. After a short sketch of the history of the disease and the anatomy of the parts affected the pathology and morbid anatomy are considered. Einhorn is quoted as stating that 91 per cent. of all perityphlitic cases are appendicular in origin and that 9 per cent. are due to primary perforation of the cæcum; these statistics are based on post-mortem examinations; but, as Mr. Treves says, surgical experience would lead us to place the cases arising from the appendix at a higher percentage of frequency. With regard to the etiology the author considers that 3 per cent. would represent the proportion of his cases of perityphlitis in which a foreign body was found in the appendix; this is in accord with general opinion at the present time; concretions are found more commonly, perhaps in 30 per cent. of the cases.

The situation of the pain felt in an attack of inflammation of the appendix is of importance; in about 70 per cent. of cases it is felt at first just above the umbilicus, and only in the remaining 30 per cent. is it found in the right iliac fossa. Occasionally pain is also felt in the left iliac fossa, and sometimes this pain on the left side may be more marked than that on the right. Mr. Treves divides the cases for purposes of description into (1) those which end in resolution; (2) those ending in suppuration; (3) very mild cases; (4) intense and acute attacks; and (5) certain peculiar forms.

The section on Diagnosis is likely to prove useful. The conditions from which perityphlitis must be distinguished are renal colic, hepatic colic, twisting of the pedicle of an ovarian cyst, torsion of a moveable kidney, general peritonitis, intestinal obstruction, colitis, carcinoma of the cæcum, hip disease, and psoas abscess; but several other conditions may simulate disease of the appendix.

The pages devoted to Treatment will probably be considered as the most important. Mr. Treves deals with the treatment (*a*) during an attack, (*b*) between attacks, and (*c*) operative interference. In the early treatment of an attack a very difficult problem is whether to give aperients; the author advises that if the onset is mild a purgative should be given at once, for he has found many times that an attack has apparently been cut short by a promptly administered aperient. In attempting to promote an action of the bowels it is best to give an enema at once; should it cause a thorough evacuation no further measure is needed; should it fail a purgative should be given without delay. If the onset of the attack be very acute and severe the administration of an aperient at once cannot be entertained. In the treatment between the attacks the digestion must be attended to and deficiencies in the teeth should be made good, for Mr. Treves tells us that he has known in many instances a set of false teeth to bring a case of relapsing perityphlitis to a favourable ending. As to the diet it should be simple and digestible; there is no pathological evidence to support the advice that the patient should especially avoid substances such as strawberries, figs, or currants, which contain minute seeds. The bowels should be made to act daily. As to operative interference Mr. Treves lays it down as a rough rule that the use of the knife is very seldom called for before the fifth day. Routine early operation is especially deprecated, for the vast majority of cases undergo a spontaneous cure and even when pus forms, in no large proportion of cases does it burst into the peritoneal cavity—according to Dr. Bull's statistics only in 8 cases out of 67. The use of the exploring needle is strongly condemned, for it is full of risk and of little value. In relapsing perityphlitis Mr. Treves advises operation if the attacks have been very numerous, even if slight; if the attacks are increasing in frequency and severity; if the last attack has been so severe as to place the patient's life in considerable danger; if the relapses have made him a chronic invalid; or if the persistence of certain local symptoms during the quiescent period renders it probable that a collection of pus exists in or around the appendix. We commend this article to all who have not already seen it in Allbutt's "System of Medicine." An index would have rendered the contents more readily available and we consider its absence a serious defect.

A Manual of Obstetrics. By A. F. KING, M.D. Seventh Edition. 1898. With 223 Illustrations. London: Henry Kimpton. Demy 8vo, pp. 574. Price 10*s.* 6*d.* net.

As an interval of only two years has elapsed since the appearance of the last edition of this work very little alteration

Digitized by Google

has been necessary in the preparation of the present, the seventh, edition, so that the book retains its former size and scope. A number of minor corrections and additions have been made and the chapter upon Puerperal Septicæmia has been rewritten. It now gives a clear review of this important subject and the most recently recommended methods of treatment, such as the administration of nuclein, the transfusion of normal saline solution, and the use of antistreptococcic serum, are adequately described and discussed. The book gives a concise and readable account of the most important facts of obstetric practice and is one of the best manuals of its size and kind. The present edition fully maintains the standard of the previous ones and the work is therefore one which we can cordially recommend to such students and practitioners as may require an outline of the principles and practice of midwifery in a compact form.

Chirurgie de la Face (The Surgery of the Face). Par FÉLIX FERRIER, Professeur à la Faculté de Médecine de Paris, Chirurgien de l'Hôpital Bichat, Membre de l'Académie de Médecine, et MM. les Docteurs GUILLEMAIN et A. MALHERBE, Anciens Internes des Hôpitaux de Paris. Avec 214 figures dans le texte. Paris: F. Alcan. 1897. Pp. 303. Prix 4 francs.

PROFESSOR F. FERRIER lectured during the session 1894–95 on the operative surgery of the face and his lectures have been arranged by two former pupils. The title hardly describes exactly the contents of the volume, for it includes, in addition to that of the face and the jaws, the surgery of the tongue, tonsils, palate, and pharynx and even of the sphenoidal sinuses. The surgery of the nerves of the face has, however, been omitted and will probably form the subject of a separate volume. A very good account is given of the various operations performed, and abundant illustrations, more than two hundred in all, assist the descriptions. The references to original papers are exceptionally numerous and British surgery appears to be given full credit for the work it has done in this department. We were interested to learn that the operation, which in this country is ascribed either to Furneaux Jordan or to Gant, for removal of the tongue by incising the cheek was described so long ago as 1832 by Jaeger. A good account is given of naso-pharyngeal adenoids and their treatment, and the description of the employment of metallic supports for rhinoplastic flaps is fully up to date. To those who can read French we recommend this little book as furnishing an interesting and useful account of the surgery of an important part of the body.

JOURNALS AND REVIEWS.

The Middlesex Hospital Journal.—The October number of this journal contains amongst other matters Dr. Voelcker's introductory address, an abstract of which has already appeared in our columns, and the continuation of Dr. Coupland's "Story of the Middlesex Hospital." Among the great names connected with the hospital mentioned in this section of Dr. Coupland's interesting papers are those of Latham, Charles Bell, and Watson.

Revue de Gynécologie et de Chirurgie Abdominale. No. 5. Septembre–Octobre, 1898. Paris: Masson et Cie.—This number contains the following articles. The Treatment of the Broad Ligaments in Hysterectomy by Angiotripsy, by M. Doyen; Esthiomène of the Anus and Vulva, by M. Verchère; Complete Prolapse of the Uterus and Vagina in a Young Virgin, by M. Fr. Stépkowski; the Treatment of Extra-uterine Gestation, by M. Paul Segond; a *résumé* of the report presented to the Congress of Gynæcology at Marseilles, October, 1898; and the Extirpation of the Cancerous Rectum through the Perineum, by MM. E. Quénu and R. Baudet. An analysis of current literature and a bibliographical index complete the number.

Analytical Records
FROM
THE LANCET LABORATORY.

HÆMATOGEN (HOMMEL'S).

(NICOLAY AND CO., 36, ST. ANDREW'S-HILL, DOCTORS'-COMMONS, E.C.)

THE interesting results following the administration of hæmoglobin in anæmia and other morbid conditions would seem to suggest this treatment as being properly classified under organo-therapeutics. The preparation here described has been spoken of favourably in this connexion. Hommel's hæmatogen is a somewhat syrupy, blood-coloured fluid, with a practically neutral taste except that due to glycerine. It coagulates on heating to a solid mass so that it is rich in albumin. On further examination we found that the preparation contained the normal salts of blood plasma. We could find no objectionable preservatives. A diluted solution exhibited the well-marked absorption spectra of hæmoglobin. The preparation is quite stable and is not repulsive on the score of taste, appearance, and smell. In some clinical trials made with this preparation the results were said to be very encouraging, indicating that it distinctly increases the amount of iron in the blood, while at the same time it acts as a nutrient by so influencing the metabolism of the body as to promote a healthy condition of the processes of nutrition. These results are in accordance with the composition and constitution of the preparation as shown in our analysis and examination.

OVO.

(THE MECREDY MANUFACTURING SYNDICATE, LTD., 248, GRESHAM HOUSE, OLD BROAD-STREET, E.C.)

This preparation needs little examination to show that it is, as described, desiccated egg. We found, however, that the desiccation had been so conducted as to preserve the properties of the nutritive substances of the fresh egg intact. Thus, on treating "ovo"—which presents the appearance of finely chopped, hard-boiled egg—with warm water for ten minutes a liquid is obtained having the appearance of a freshly whipped egg. Moreover, the albumin is in a soluble state and uncoagulated, for on filtering the liquid with the aid of pressure a fluid is obtained which on boiling turns semi-solid. When examined for objectionable preservatives the results were negative. The preparation is identical with egg, except that the moisture has been reduced carefully by a process which does not alter the constitution of the proteids. It is erroneous, therefore, to describe "ovo" as an egg substitute.

PROTENE PREPARATIONS.

(THE PROTENE CO., LTD., 36, WELBECK-STREET, CAVENDISH-SQUARE, W.)

The basis of these preparations is "protene," a powder occurring in small grains which is but little soluble in water. It is essentially a nitrogenous compound identical in composition with the casein of milk. Our analysis gave the following results: nitrogenous matters, 80·00 per cent.; non-nitrogenous matters, 11·93 per cent.; mineral matter, 4·37 per cent.; and moisture, 3·70 per cent. The mineral matter consisted almost exclusively of phosphates identical with those in milk. Protene, indeed, is described as a form of dried milk with the fat and sugar eliminated, the flesh-forming and bone-forming substances being alone retained. It is clearly a powerful food substance and admirably adapted for raising the nitrogenous value of farinaceous or other foods. Protene flour (No. 2) gave the following results on analysis: nitrogenous matters, 76·73 per cent.; non-nitrogenous matters, 13·59 per cent.; moisture, 3·27 per cent.; and mineral matter, 6·41 per cent.

Digitized by Google

The increased amount of mineral matter here is due to a small quantity of added carbonate of soda which renders the protene to some extent soluble. Protene bread gave the following results on analysis: moisture, 42·43 per cent.; nitrogenous matters, 51·87 per cent.; carbohydrates, 2·40 per cent.; and mineral matter, 3·30 per cent. The bread contains a trifling quantity of starch. It presents a satisfactory spongy texture and should serve as a valuable and palatable food in those cases where sugar-producing substances are contra-indicated. Lastly, protene is the basis of some excellent biscuits which differ from the foregoing preparations in containing fat. They possess a very agreeable flavour and are desirably "short." We consider "protene" a valuable and important addition to dietetics in affording a means of adding considerably to the nutritive properties of special foods. The application of protene in accentuating the nutrient properties of various forms of food is well illustrated in the following preparations which are made: "protene household flour," "protene luncheon biscuits," "protene training biscuits," "protene medical biscuits," and "protene fancy biscuits." Painstaking research has established that the proteids of milk are amongst the most easily assimilated, and since these form the basis of "protene" preparations, many of which contain no less than 50 per cent. of proteid, it follows that they must possess a high degree of really nourishing property.

(1) PLASMA NASAL TABLETS; (2) MENTHOLATED THROAT TABLETS.

(PARKE, DAVIS AND CO., 21, NORTH AUDLEY-STREET, W.)

Both these formulæ are of well-known value and the convenience of the tablet form containing the ingredients in reliable ratio is obvious. The composition of the "plasma nasal tablets" is as follows: sodium chloride, 5½ gr.; sodium sulphate, 1½ gr.; sodium phosphate, ¼ gr.; potassium chloride, ⅔ gr.; potassium sulphate, ¼ gr.; and potassium phosphate, ⅓ gr. The tablet when added to 2 oz. of lukewarm water gives a solution of the same density as blood-serum. The addition of a trace of menthol is an important feature, which gives the solution sedative properties. It is therefore well adapted for application to the nasal cavities. The throat tablets are also mentholated and contain as well an approved quantity of cocaine hydrochlorate, aniseed oil, benzoic acid, and eucalyptol. They are very agreeable in inflamed conditions of the throat, mildly stimulating the secretion and relieving irritation.

ESSENCE OF COCOA.

(JOHN TORDOFF AND SON, BRADFORD AND 21, MINCING-LANE, E.C.)

This is a well-prepared cocoa satisfactorily miscible with hot water, the resulting infusion possessing a rich cocoa flavour. According to our analysis more than one-third of the indigestible fat in raw cocoa has been removed in this preparation. The amount of mineral matter was normal, though it showed an alkalinity suggesting a special method of manufacture, which tends to increase the digestibility of the cocoa.

PAPINE.

(ROBERTS AND CO., 76, NEW BOND-STREET, W.)

"Papine" is described as the anodyne or pain-relieving principle of opium the narcotic and convulsive elements being eliminated. The name suggests a corruption of "papaverine" which is anti-tetanic and hypnotic. The preparation proved to be an alcoholic solution coloured with cochineal and exhibiting a slightly acid reaction. On neutralising with ammonia and extracting with chloroform a residue was obtained which gave a blue reaction with Fröhde's reagent (ammonium molybdate dissolved in sulphuric acid), while an abundant mahogany-coloured precipitate was obtained with a solution of iodine in potassic iodide. One fluid drachm is said to be equal in anodyne power to ⅛ gr. of morphine. It would appear to be without the drawbacks of opium, since it is stated it has less tendency to cause nausea, vomiting, and constipation.

FORTUNA NATURAL MINERAL WATER.

(SANDERS, REHDERS AND CO., 108, FENCHURCH-STREET, E.C.)

The spring from which this water is drawn is situated in a valley between the Vogel and Taunus mountains in Germany, not far from Nauheim. It is only slightly mineralised and contains no added salts. The total mineral matter, in fact, amounts only to 1·54 grammes per litre, of which 0·8 gramme is common salt, the balance consisting of lime salts, the carbonate and sulphate. The water possesses in regard to taste the characteristics of a pure natural water. It is quite free from organic matter. On examination with the spectroscope some evidence was gained of the presence of lithium. The water is pleasantly sparkling and bright and well adapted for table purposes. Its composition lends support to the statement that it is an "absolutely natural" mineral water. It contains a very small proportion of mineral salts, an excess of which distinguishes many other "natural" effervescing waters of the same class.

DOUBLE CYANIDE GAUZE (LISTER).

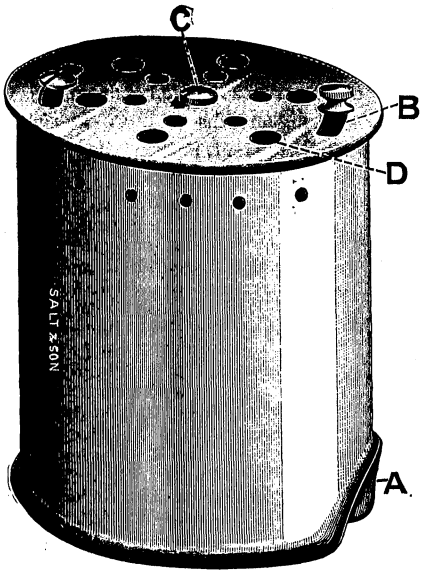
(JOHN MILNE, LADYWELL, LONDON, S.E.)

We have carefully tested a specimen of gauze submitted to us, and the results were in accordance with the directions first indicated by Lord Lister for impregnating the material with the double cyanide (mercury and zinc). When prepared with due care the application of such a gauze is unattended with mercurialism. Such is claimed to be the case, at any rate, with the dressing made by this firm.

OLD BLENDED SCOTCH WHISKY.

(J. HEGINBOTHAM, 47, MARKET-STREET, STALEYBRIDGE.)

The analysis of this whisky was as follows: alcohol, by weight 41·05 per cent., by volume 48·48 per cent., equal to proof spirit 84·96 per cent.; extractives, 0·16 per cent.; volatile acidity, *nil;* reducing substances (reckoned as sugar), 0·15 per cent. The spirit was smooth to the taste which gave no suggestion of the presence of any crude product. It contains a minimum of extractive matters, while the acidity was hardly measurable. It is evidently a pure spirit and skilfully blended.



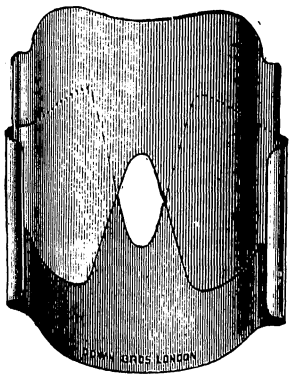
New Inventions.

METAL A.C.E. INHALER WITH A SIMPLE MEANS OF VARYING THE AIR-SUPPLY.

THE mask is lightly made of German silver nickel-plated and the general construction is fairly represented by the illustration. The rim is fairly accurately adapted to the contour of, and has a recess shown at A for, the nose. The plate closing the end of the mask is pierced by a number of holes (D) and the stud B is attached to an internal plate similarly pierced and rotating on the pivot C. Very free access of air is allowed when the holes in the internal and external plates coincide and the supply is regulated by moving the stud B whereby partial or complete closure of the holes can be effected at will. There are also apertures around the upper part of the mask, as shown in the illustration, to allow of a moderate continual air entry, independently of the regulated supply and of that admitted under the edge of the inhaler. Close under the perforated plates is placed a sponge of coarse texture. Besides the A.C.E. mixture this inhaler is well adapted for the administration of other mixtures containing a larger proportion of ether than does the A.C.E. One can very conveniently add ether to any mixture which is being administered, of course regulating the air-supply accordingly. Even ether alone may easily be inhaled from this mask. It is often of advantage to first give a little A.C.E. on a Skinner's mask

Digitized by Google

and then in two or three minutes to change to this inhaler, having its air apertures patent at first and gradually restricting the air-supply as is found necessary according to the age and condition of the patient. The sponge should occasionally be removed and squeezed to get rid of superfluous alcohol and chloroform remaining over after the evaporation of the ether. If pure ether is being given it is advisable to prevent access of air under the free edge by means of a cloth.



The chief advantages of the inhaler are—(1) its exceeding lightness and simplicity and the ease of sterilising it; (2) its suitability for administering besides the A.C.E. other mixtures stronger in ether or even ether alone; and (3) the ability to regulate to some extent the air-supply. I find it of great use and would not be without it, especially when anæsthetising old people. This inhaler has been made to my instructions by Messrs. Salt and Son of Birmingham.

W. J. McCARDIE, B.A., M.B., B.C. Cantab.,
Anæsthetist to the General Hospital and to the Dental Hospital, Birmingham.

AMPUTATION RETRACTOR.

ALL surgeons, in bone amputations, of muscular limbs especially, know the difficulty assistants have in keeping the flaps out of the way of the saw and their fingers out of danger; also the difficulty of holding firmly the proximal part of the bone, as in the thigh. When the operation has to be performed with only one assistant or with unskilled help these difficulties are accentuated. Some three years ago I had made by a local tinsmith an instrument which my colleagues and I have continued to use with advantage in hospital work. This instrument Messrs. Down Bros. have been good enough to make in a more finished style, as depicted in the illustration. The retractor consists of two blades, which are concavo-convex from side to side, and when fitted together, as in the illustration, practically form half of a cylinder with a hole in the centre; this hole is due to the wedge-shaped piece which is absent from each blade. When about to be applied the two blades are separated entirely and the female (lower) one is placed so that the bone lies in the apex of its notch; the male blade is passed to the other side of the limb and then pushed into the grooves of the female one and thus the bone is encircled by the retractor. The flaps are now covered by the metal and the instrument is held easily by the edges which form the grooves at the sides. In the case of two bones one bone fits into the apex of one notch and the other into that of the companion retractor. An ordinary surgical retractor may be placed between the bones on the proximal side to retract all the tissues between if necessary. By pressing the flat end of the female blade firmly on the operating table the bone can easily be held as if in a vice and by pulling towards the body the flaps can be retracted to any extent wished.

The advantages which this instrument presents are—(1) protection of the flaps from damage; (2) perfect exposure of the bone to be divided; (3) absolute and easy fixation of the bone; (4) reduction in the number of assistants required; (5) perfect protection of the assistants' fingers; and (6) simplicity of cleansing the instrument by boiling or scrubbing.

I feel indebted to Messrs. Down Bros. for their ready help and for their careful construction of the instrument.

Preston.

HEALTH OF BELFAST.

AT a meeting of the Public Health Committee, held on Oct. 27th, it was reported that 125 cases of typhoid fever were notified during the week, the numbers in the previous six weeks having been 149, 151, 172, 164, 247, and 270. Nine cases of diphtheria were also notified during the same week. The following paragraph, from an account of this meeting, appears in the public press and is not calculated to keep up pleasant relations between the Public Health Committee and the medical profession: "The Infectious Diseases Notification Act and its operation were again brought forcibly to the front by the case of a person who had been notified as suffering from typhoid fever and who having unfortunately succumbed to the illness was returned as having died of bronchitis." At the last meeting of the combined Public Health and Improvement Committee a report was presented by the borough surveyor and the executive sanitary officer in reference to the resolution passed on Sept. 20th to the effect "that a systematic test of all the drains in the city be made and that the head officers of the Public Health and Improvement Committees report what additional officers are necessary for this purpose, and that such officers be appointed and a weekly return of the drains so tested be made to the above committees." At the meeting on Oct. 27th the two officers mentioned reported that the enforcing of this resolution would effect one of the most sweeping changes ever proposed by any committee of the corporation and that in their opinion it practically amounted to the sanitary reconstruction of the drainage of the great majority of the houses within the city. They say, assuming that Belfast contains at present about 70,000 houses, and that one inspector and an assistant can thoroughly test and report on the drainage of six houses per day, so as to be available for legal evidence, thirty-nine inspectors with their assistants and workmen would be required (exclusive of expenses involved in conveying testing apparatus, &c.) to do the work in a year. It is well to be able to state that notwithstanding a determined effort to oppose those who are working so hard to get the sanitary condition of the city made right—a state of affairs due to the neglect of past years—the following resolution was carried: "That three additional plumbers be appointed in conjunction with the four already in the surveyor's department to examine and test all drains, each of the seven to have an assistant." No more serious indictment was ever brought against any city than that made by the city surveyor and the executive sanitary officer of Belfast when they report that to carry out a resolution of the city council to make a systematic test of all the drains in Belfast "practically amounts to the sanitary reconstruction of the drainage of the great majority of the houses within the city." If this is true is it any wonder that typhoid fever has been so prevalent in Belfast? but the only solution—and it will take time and money—is to begin at once to make matters right. Every credit is due to those members of the Public Health and Improvement Committees (lay and medical), who are determined that a thorough attempt shall be made to improve the present sanitary state of Belfast.

THE LANCET.

LONDON: SATURDAY, NOVEMBER 5, 1898.

THE new and elaborate Vaccination Order issued by the Local Government Board bears many marks of careful consideration and of great administrative skill and experience on the part of its draughtsmen. Its provisions take cognisance both of difficulties which have been experienced in the past and of new difficulties which may be expected to arise in the immediate future in consequence of the coming into operation of the new Act and of the efforts which are already being put forth by those whose distorted mental vision has led them to make opposition to vaccination the main purpose of their lives.

A circular letter to boards of guardians accompanies the order and points out, *inter alia*, that with the exception of Section 2 (the Conscience Clause), which is already in force, the new Act will be in operation from Jan. 1st, 1899 to Jan. 1st, 1904; that the Board are now empowered to make rules with respect to the duties and remuneration of public vaccinators, even if already in office; that public vaccination stations will be abolished from the end of this year, unless under Section 7 of the new Act the Board deem it expedient to require guardians to provide such stations owing to serious risk of small-pox prevalence or to other exceptional circumstances, though the letter avoids, perhaps wisely, any attempt to indicate what might be considered such "other exceptional circumstances"; that domiiciliary vaccination will take the place of stational vaccination; that the duties and remuneration of public vaccinators and vaccination officers therefore require revisal; that without any Order issued by the Local Government Board and without any instructions by boards of guardians the power and duty of taking legal proceedings to enforce the Vaccination Acts are vested in the vaccination officer; that an order under Section 31 of the Act of 1867 directing the vaccination of a child shall not be made on any person who has previously been convicted of non-compliance with a similar order relating to the same child; and that no proceedings under Section 31 shall be taken against a person already convicted under Section 29 on account of the same child until he or she has reached the age of four years.

The Order itself consists of thirty-two articles and five schedules. Article I. provides that the validity of existing contracts with public vaccinators and the appointment and tenure of office of existing vaccination officers are not interfered with excepting that the duties and remuneration must be in accordance with the new Order.

Article 3 deals with the remuneration of public vaccinators and Article 20 with that of vaccination officers. The scheme in the two cases is similar in principle though not identical in operation. Each official is to receive, first, a small payment in respect of every child as to whom he has any kind of official duty under the Acts, whether such child ever be vaccinated or not, and, secondly, a larger and additional payment for each successful vaccination with which he has to do. With regard to the vaccination officer this first small payment means a minimum capitation grant of threepence for every child born within his district, he having certain duties with regard to all of them. For the public vaccinator the first and smaller payment is to be a shilling as a minimum, but the basis of payment is not nearly so wide. His duties will begin with children four months old unless where he is called in earlier by the parent, and so far as this capitation payment is concerned there will be several important deductions. He will receive nothing for children not included in the lists furnished to him by the vaccination officers, and such lists will exclude all children as to whom a certificate of conscientious objection has been duly lodged, or whose vaccination, or insusceptibility, or unfitness has already been certified.

The second or additional payment refers, in the case of both officials, to successful vaccinations, and, in the case of the public vaccinator, to successful revaccination of children over ten years old or of persons who have not been vaccinated within the previous ten years. The minimum fee to the vaccination officer will be 9*d*. (besides additional payments which the Board may direct for extraordinary services) and to the public vaccinator 5*s*. for domiciliary vaccinations or revaccinations and 2*s*. 6*d*. for vaccinations of persons other than children, or for revaccinations, done at his surgery or elsewhere. For workhouse vaccinations the fee is similarly to be 2*s*. 6*d*.

In considering the adequacy of these fees to the public vaccinator various facts have to be kept in mind. What we have for convenience called the capitation fee is obviously intended to remunerate the officials for work requiring to be done by them under the Statute and Order but which yet may not result in the performance of vaccination. In places where the new law is honestly carried out, where objectors go before the magistrates to get relief and then lodge their certificates of conscientious disbelief with the vaccination officer, almost every domiciliary visit should mean a domiciliary vaccination, and here the minimum payment of 6*s*. (1*s*. plus 5*s*.) would be for the operation and one subsequent visit, and also for any other visits which the public vaccinator might think necessary. But the readers of an anti-vaccinationist print are, we observe, advised not to apply for any certificate of relief and not to submit to vaccination when the public vaccinator calls. If this advice be followed in any district the effect will be, on the one hand, to reduce very greatly the average fee received by the public vaccinator for each domiciliary visit, but, on the other hand, to increase greatly the total amount received, as the number of names in the lists submitted to him by the vaccination officer will obviously be all the greater according as the certificates of conscientious objection are the fewer. This is a contingency which, we fancy, may cause the organ of the Anti-vaccination League to feel itself in a dilemma. Nothing could well be more abhorrent to it than an increase in the remuneration of public vaccinators, while at the same time it is evidently most anxious to make as much trouble as possible by inciting

Digitized by Google

to the refusal not only of vaccination but also of the relief provided by the Conscience Clause.

It is to be noted that the payments above mentioned are minimum payments. In a thickly populated place, where the lists sent to the public vaccinator may contain many children whose homes are within a short distance of his own residence, obviously, other things being equal, the minimum fees will be much more likely to be adequate than in the country, where a single domiciliary visit, whether or not it results in a vaccination, may involve a drive costing several shillings and taking much time. In rural districts, therefore, the fees should rule higher than in towns, especially as everything must be covered by the fees, the Order making no provision for payment of hires or allowances for long journeys. As in the case of many medical appointments, the short and the long distances must be accepted alike by the holder of the office, and he should therefore see that the fees are so fixed as to cover reasonably all contingencies.

Here we regret to note that the public vaccinator will be at a great disadvantage as compared with the vaccination officer. The former is dismissable on twenty-eight days' notice, while every vaccination officer appointed under the new Order "shall continue to hold office until he shall die, or resign, or be removed by the guardians, with Our consent, or by Us, or shall be proved to be insane by evidence which We shall deem sufficient." The words of the Local Government Board, "with Our consent," will afford a great security to the holder of the office in making any request for increase of fees. The public vaccinator is to have no such protection, and we must assume that the central authority had no power to give it to him, otherwise it could hardly have made such an invidious distinction between the two servants. Let it be understood that we do not grudge the vaccination officer his security. On the contrary, it is entirely in the public interest as well as in his own interest, but it would also be in the public interest that the public vaccinator should be similarly dealt with. We sincerely trust that in every district, and especially in rural districts where the minimum fees must be least satisfactory, the standard of professional conduct will be such as to make the public vaccinator safe in insisting on a reasonable reward for his services. It is true that the payments "shall, subject to the above provisions as to the minimum, be of such amount ..... as may be fixed in the contracts approved by" the Local Government Board, but if a medical man were willing to accept office on the minimum scale where another scale ought to be in force it might be difficult for the central authority to interfere.

Articles 6 to 9, inclusive, deal with the duties of the public vaccinator, which are further specified in the third Schedule. His domiciliary visits must be made between 9 A.M. and 4 P.M., and he must give twenty-four hours' notice. His visit must be made within a fortnight after receiving the notice from the vaccination officer or a request from the parent. The Schedule of Instructions to Public Vaccinators contains some clauses which ought to apply to every vaccination done by every private medical man, and which are so important that we quote them here.

4 The public vaccinator must keep such record of the lymph he uses for vaccinating as will enable him always to identify the origin of the lymph used in each operation. He must not employ lymph supplied by any person who does not keep an exact record of its source.

5. The public vaccinator must keep in good condition the lancets or other instruments which he uses for vaccinating, and he must not use them for any other purpose whatever. When he vaccinates he must cleanse and sterilise his instruments after one operation before proceeding to another and must always, when vaccinating, have with him the means of doing this. When once he has unsealed a tube of lymph he must never attempt to keep any part of its contents for the purposes of vaccination on a future occasion. Under no circumstances should the mouth be applied directly to the tube in which the lymph is contained for the purpose of expelling the lymph. In the case of ordinary capillary tubes an artificial blower may properly be used for this purpose.

6. Vaccination should at every stage be carried out with aseptic precautions. These should include: 1st, the cleansing of the surface of the skin before vaccination; 2nd, the use of sterilised instruments; and 3rd, the protection of the vaccinated surface against extraneous infection both on the performance of the operation and on inspection of the results.

Advice as to the precautions to be taken in this respect until the scabs have fallen and the arm has healed should always be given to the person having the custody of the child.

7. In all ordinary cases of primary vaccination the public vaccinator must aim at producing four separate good-sized vesicles or groups of vesicles not less than half an inch from one another. The total area of vesiculation resulting from the vaccination should not be less than half a square inch."

Articles 10 to 15 inclusive deal with the appointment of vaccination officers. Wherever the guardians or the Local Government Board think the number of officers insufficient for the district additional officers shall be appointed, and temporary assistance shall be provided when necessary owing to an outbreak of small-pox or other cause. When a vacancy occurs the office shall be filled up without delay, and if this cannot be done forthwith a person must be appointed temporarily. Under the heading of "Duties of Vaccination Officers" (Articles 25–28) there is further indication of the Board's attitude as to legal proceedings by that officer.

"He shall, when required by the guardians, give them full information as to any legal proceedings taken by him as vaccination officer; and, subject to the provisions of the Vaccination Acts, 1867 to 1898, and of this Order, shall obey all lawful orders of the guardians which are applicable to his office."

The officer here is not to wait for instructions by the guardians to prosecute, or to ask for instructions, or even to report his proceedings as a matter of course. His sole duty to the guardians in this connexion is that "when required" he shall "give them full information" as to his doings. It will be interesting to note how those boards of guardians which in the past have systematically and ostentatiously neglected their duties under the Vaccination Acts will receive this very plain intimation that the vaccination law can be administered in spite of them. Not only can they not prevent the officer doing his work, but they are bound (Article 29) to pay the costs of his doing it and also (Article 28) to report to the Local Government Board if he is not doing it, and the Board (Article 16) has the power to remove any officer.

We have already seen that it is the duty of the

Digitized by Google

guardians, with the approval of the Local Government Board, to fill up vacancies. No article in the Order deals with the case of guardians refusing to fill up a vacancy. In such an event perhaps the Board would itself make the appointment. That would certainly be better than sending the guardians to prison as was done long ago in the Keighley case, where the local authority refused to administer the law. But if the Board should have to take any proceedings it would certainly be greatly strengthened by the fact that the Conscience Clause removes the last shred of reasonable complaint from the path of the most obstinate anti-vaccinationist. A board of guardians which would endeavour to prevent a fair trial of the new law by such indirect means as are here indicated would be most unlikely to receive public sympathy, excepting in places which have come to regard law-breaking as a communal virtue, and notwithstanding the long crusade of the Anti-vaccination League such places are not yet numerous, if, indeed, they are to be found at all, in England.

WE published last week a table of the entries of students for the year 1898-99. An ordinary person would have to be endowed with very special intelligence to grasp the full significance of tables purporting to give the comparative facts in successive years as to the entries of medical students in the various medical schools of London and the provinces, for medical education is now made up of many different elements and includes a great variety of subjects. Besides, in London especially, certain of the schools make valuable provision for special courses which are as a matter of fact often taken by persons who receive their ordinary medical education elsewhere. Thus, King's College, with its classes for special courses, figures in the table as having a larger total than either St. Bartholomew's or Guy's or any other hospital and yet has a com aratively small entry for the full course. These special courses constitute an important feature in the efficiency of schools, especially schools for those who are contemplating the taking of degrees or any other departure from the ordinary curriculum of medical education. Time was when two or three lecture-rooms and a dissecting-room constituted the plant of a medical school. All this is changed. The development of histology, biology, and chemistry, with new and more practical methods of teaching them, have trebled the cost of such plant, and the completeness with which such special courses are provided for and the efficiency of the teacher who gives them count for much in the attraction of a school. Thus one laboratory or one or two good teachers in special subjects may give character to a school and draw a large number of students to it. In the table of entries for the current year, 1898-99, the whole number of entries for special courses in London is 556—almost as large a number as the entries for the full medical course. It is not unreasonable to suppose that in the new developments of medical education likely to arise out of the reconstruction of the University of London there may be some further specialisation of work in the various schools, with advantage alike to them and to the cause of medical education.

Perhaps the chief interest of the table is in its first column, which seems to show as regards London a considerable increase over the numbers entering in the two previous years. In 9 out of the 12 London schools there is an increase as compared with the previous year. But it is not very considerable and in some of the larger schools, the entries at which perhaps are the best guide to the rate of increase, there is a diminished number of entries. This is the case at Guy's, the London, and University College Hospitals. The last two columns of the table, it is true, show an increase of the total entries in 1898-99 as compared with 1897-98, of 345. This may seem rather serious to those who had been hoping that the undue influx into the profession which has been going on of late years was at least moderating. Such persons need not be over-anxious so far as this particular table is concerned, for a careful study of it will show that the increase of 345 is largely explained by the large number of entries for the special courses at King's College to which we have already alluded, no such return having been included in the table of last year's entries.

It is interesting to notice the activity of the provincial schools. The entries at the University of Cambridge for full students—127—exceed those of any other English school, metropolitan or provincial. Those at Owens College, Manchester, 66 in number, with an almost equal number of entries for special classes, make the total entries much larger than those of any other provincial school. Those of University College, Liverpool, come next. The whole entries for the provincial schools amount to nearly half of the whole of the entries for the metropolitan schools. As to dental students the majority of medical schools do not have any special courses for this department of practice. In London and in the provinces, respectively, only five schools provide dental courses. The entries for these in London were 93 and for the courses in provincial schools 58.

THE second trial of JOHN LLOYD WHITMARSH at the Old Bailey for the murder of ALICE BAYLY terminated on Oct. 26th. The jury, as we have already announced, found the prisoner guilty of wilful murder and the judge sentenced him to death. As, however, it was certain that the death sentence would not be carried out, if only because of the strong recommendation to mercy preferred by the jury, we decided to await the Home Secretary's decision before commenting at length upon the case. The death sentence has now been commuted. It will be remembered that at the previous sessions of the Central Criminal Court the jury were unable to agree.

The indictment charged that on June 18th the prisoner performed an illegal operation upon ALICE BAYLY for the purpose of procuring abortion. The history of the case is remarkable (1) in that the means adopted by WHITMARSH included, besides operative interference, the local application of a salt of mercury; (2) that it was the first case of murder in this country in which the accused was legally constituted a competent witness; and (3) that the prisoner was convicted of the capital offence of murder. The cause of death of the unfortunate woman who paid the penalty of sacrificing her life for her participation in the crime was not challenged by the counsel for the defence.

Digitized by Google

The evidence of Dr. STEVENSON and Mr. BOND, the chief medical witnesses for the prosecution, placed the matter beyond all reasonable doubt. There was ample testimony that the deceased succumbed to the combined effects of septicæmia and mercurial poisoning, and it appears equally clear that the latter was introduced into the system by a topical application. Whether this was done with the intent to produce a local irritant effect and thus to ensure the intended consequences of instrumentation or with a view to prevent sepsis seems doubtful. We may remark parenthetically that some years ago a Belgian was convicted and sentenced to fifteen years' penal servitude at the Old Bailey for having procured abortion by applying acid nitrate of mercury to the cervix uteri. The victim in that case succumbed to acute mercurialisation and not to septicæmia.

WHITMARSH, on counsel's advice, did not give evidence before the coroner, nor did he attempt previously to the trial to exculpate himself save by a direct denial as expressed in the following terms: "It is an abominable lie." We do not question that counsel would in his discretion advise what he considered best to serve the interests of his client; at the same time it must be conceded that there was much force in Mr. GILL'S accentuation of the fact, in his conduct of the prosecution for the Crown, that "the prisoner had not given any explanation although he had had every opportunity of giving one." If the prisoner knew that he was guilty we can understand that he would feel that silence on his part would be the best safeguard against self-incrimination; for any statements made by him would clearly lead to further investigation for the purpose of proving the truth or falsity of the same. But at the trial he would be on safer ground, although submitting himself to the ordeal of a cross-examination, for whatever the forensic ability of counsel and however damaging the answers elicited might be the effect would necessarily not be commensurate with the direct testimony of disinterested witnesses. We subscribe to the proposition that the new Act of Parliament which permits prisoners to give evidence on oath will in the main be a help to the innocent and a pitfall to the guilty. At the same time it is not an unmixed good, for it is possible that juries may view with distrust the presentment of a prisoner's innocence by counsel, unless supported by the prisoner's appearance in the witness box. Nor on moral grounds can it be unconditionally approved, since obviously it will be a powerful incentive to perjury. The late sessions at the Old Bailey will be memorable in that two persons were convicted of murder after denying on oath their guilt, and yet in each case the circumstantial and direct evidence for the prosecution thoroughly warranted the verdicts. We are also of opinion that Mr. Justice BIGHAM justly admitted the dying declaration of the deceased woman BAYLY that attempts had been made upon her to procure criminal abortion; but we have serious misgivings as to the value of such statements, being far from satisfied that the belief of approaching death will always nullify the human tendency to minimise one's own offence and to shift the responsibility to others' shoulders. Besides, on medical and psychological grounds a person whose decease is judged to be imminent is not in a fitting state to carry on such intellectual processes as are worthy to form the basis of evidence whereby the life of an individual may be sacrificed or his liberty taken away.

Lord BRAMWELL'S judgment that a person who by illegally procuring abortion sacrifices the life of the woman is guilty of murder has not been reversed or, as far as we remember, been appealed against. Judges, however, have generally shown a tendency to a lenient interpretation of the law by directing juries that they might find circumstances which would warrant them in returning verdicts of the minor offence of manslaughter. We commend the singularly clear and logical charge delivered by Mr. Justice BIGHAM at the trial of WHITMARSH. The learned judge said: "If a person in committing a felonious act compasses the death of another he is guilty of murder unless he could not reasonably infer that death would result as a consequence of the act." Now, it must be admitted that every medical man knows that the procuring abortion is fraught with danger to the life of the patient even where precautions are taken to avoid the incidence of septic infection. How infinitely more dangerous, then, is the procedure where no such measures are adopted. The guilt of WHITMARSH having been proved we fail to see any extenuating circumstance, save that he had every reason to desire that the death of his poor accomplice should not ensue. There was, of course, in his crime an absence of malice prepense which is generally held to be the essence of homicidal intent; and for this reason we share in the relief which it is known is felt by the public at the reprieve which has been extended to the wretched man. But legally the death sentence was justified. If only to meet cases of criminal abortion it would be well if our penal code recognised "degrees of murder."

Annotations.

"Ne quid nimis."

THE NATIONAL ASSOCIATION FOR THE PREVENTION OF CONSUMPTION AND OTHER FORMS OF TUBERCULOSIS.

THE following letter has been sent on behalf of the Association, signed by Sir Samuel Wilks, Sir William Mac Cormac, and Sir William Broadbent, to the Chairman of the London County Council:—

"The attention of the Organising Committee of the National Association for the Prevention of Tuberculosis has been directed to the recommendations of your Public Health Committee with regard to the institution in London of an administration for the prevention of disease conveyed by milk and meat. Our Association is more particularly interested in the question of the prevention of tuberculosis, and we understand that your Committee recommends that the Council should be empowered to take the necessary steps for preventing the sale of tuberculous milk and meat. On behalf of our Association we beg to state that we are strongly of opinion that there is urgent necessity for such measures, and that if the Council takes steps to prevent the sale of tubercle-infected milk in London and to ensure the proper examination of meat by the substitution of public for private slaughter-houses there is every prospect of reducing the present mortality from tuberculosis, especially among the poor, who more particularly suffer from the effects of milk and meat of dangerous quality. We regard it as fortunate that the recommendations of the Royal Commission on Tuberculosis are being so promptly considered by a body which has always manifested the greatest interest in the

Digitized by Google

public health. We are much impressed by the conviction that the action of the London County Council in this matter will set an example which is likely to be followed throughout the kingdom. We therefore respectfully urge upon your Council the eminent necessity of adopting the recommendations of your Public Health Committee."

A recent leading article in our columns advocated strongly that the recommendations of the Public Health Committee of the London County Council with regard to securing a pure meat- and milk-supply for the city should be immediately adopted, and so universal is this opinion among all who, like the signatories of the above letter, understand what are the real factors in the spread of disease, that we can hardly suppose that the County Council will do otherwise.

THE MILK-TRADE AND DIPHTHERIA.

ON Oct. 28th Evan Morris, a milk-seller of New North-street, Holborn, was summoned at Clerkenwell Police-court on three counts for not immediately upon an outbreak of diphtheria within the building in which he kept milk giving notice of the same to the London County Council, for not removing the milk immediately on the outbreak of the disease, and for keeping milk in the building before it had been disinfected. On the first summons defendant was found only technically guilty, as he had given notice to the Holborn Board of Works. On the second summons it was proved that defendant's wife had served milk in the shop after removal of the same and the utensils had been ordered by the London County Council's inspector. Costs only were ordered on the third summons, but on the first there was a penalty of 5*s*. and 2*s*. costs and on the second 5 guineas penalty and 2 guineas costs. We do not think this penalty severe. Milk is such a typical breeding ground for the diphtheria bacillus and such a universal vehicle for the conveyance of infection to young children, who are the class of the community more fatally affected by the disease than any other, that too much care cannot be exercised in the prevention by every possible means of the contamination of this essential article of diet. We make every allowance for the difficulty which the lay mind has in realising the importance of the hygienic measures which have been laid down by scientific men for the preservation of the health of the community, but it must be shown that non-compliance with such regulations will result in punishment whether the offenders understand the reasons for them or not.

OPTICAL DIPLOMAS.

A NOTICE appeared in the *Times* of Oct. 31st to the effect that the Spectacle Makers' Company has been engaged for some months past in perfecting a scheme for the granting of optical diplomas to those who pass an examination. The committee has appointed as examiners Professor Silvanus Thompson, Dr. G. Lindsay Johnson, and Mr. G. Paxton. The examinations are being held this week and it is stated that as many as 150 candidates will attend. The presence of Dr. Lindsay Johnson on the Board of Examiners confers an interest upon the examination which it would not otherwise possess and leads us to make a few comments upon it. There can be no doubt that Dr. Lindsay Johnson is in every way well qualified for the duties of an examiner, a post which we have not the slightest doubt was entirely unsolicited on his part. He is a distinguished graduate of the University of Cambridge, has seen much eye practice, and has written various papers of interest and value. His coadjutors are Professor Silvanus Thompson, a gentleman of high scientific status, and Mr. G. Paxton, who is a cultivated and intelligent optician. That an examination should be established to test the knowledge of those to whom the manufacture of instruments of precision, such as are daily ordered by the ophthalmic surgeon, is entrusted is reasonable enough. It is right that they should show that they understand the object for which such instruments are prescribed, but it will require, we think, much care on Dr. Lindsay Johnson's part to ensure that the examination for which he will be held responsible is confined to the strictly physical aspect of the subject and that it does not infer a kind of irregular professional status and lead those who have passed it successfully to conclude that they are by their capability of recognising the nature and extent of the physical defects of their customers' eyes thereby qualified to give an authoritative opinion in regard to the treatment to be adopted. We note in the *Optician* of Oct. 27th, 1898, that at a special meeting of the Spectacle Makers' Company Mr. Maw called attention to a custom which was gaining ground—that of opticians selling drugs. It seems to us not a very long step to the employment of certain drugs for what might probably be regarded by a zealous optician as purely optical purposes but which would really be a serious infringement of the law and might lead to very unpleasant results. In some respects, therefore, it is perhaps as well that the guidance of the examination should be partly in the hands of a medical man of good standing who will be able to point out to the Company, his co-examiners, and the candidates what is or is not in the province of the optician. Still the ground is a somewhat dangerous one, and we shall look with interest at the style of examination inaugurated by Dr. Lindsay Johnson and the kind of question to which he expects an answer to be given by those who present themselves for the purpose of obtaining the diploma.

"VICARIOUS URINATION (P)."

UNDER this heading a most extraordinary case is reported in the *Canada Lancet* (October) by Dr. Q. T. Rice, of Woodstock, Ontario. The patient, aged thirty years, a daughter of a farmer, of a somewhat nervous temperament and rather weak intellect, had been attacked three years before with a cystitis of two or three weeks' duration, the attack being somewhat severe, there being complete atony of the bladder, necessitating the use of the catheter during that period. This attack gradually subsided, though considerable tenderness remained. One year after this attack she was again laid up with involuntary twitchings or spasms of the whole body; accompanying this attack there were a number of discolourations of the right leg and thigh, extending almost entirely over the limb but without tenderness. This after a few weeks gradually disappeared and the patient regained her ordinary health. In the following year the atony of the bladder returned. The patient was again obliged to resort to the use of the catheter three times a day, about ½ oz. of urine being withdrawn upon each occasion. During this time her general health suffered severely. The feet then began to swell slightly and a peculiar complication set in. The secretion in the bladder gradually diminished but was compensated for by an exudation of fluid from the anterior portions of the lower limbs between the knee and ankle. This fluid was voided regularly three times a day, the amount gradually increasing, the average being about from 30 oz. to 40 oz. per day. The fluid simply oozed from the skin without any abrasion of the skin or discolouration or even the slightest œdema being present; the patient would realise that the fluid was about to issue and would place her feet upon a stool and a dish beneath the heels. Dr. Rice was present at one time when it began and can therefore vouch for the correctness of the statement. The fluid was of an amber colour, similar to healthy urine; its specific gravity was 1010; there was an absence of albumin or sugar; it had a strong smell of urine upon boiling, with a distinct ammoniacal smell after

Digitized by Google

standing; examination also showed the presence of uric acid. After this symptom showed itself the patient's health rapidly improved and became fairly well established, so that she had little to complain of except the inconvenience caused by this peculiar phenomenon. This condition lasted about two months, when, after an unusually large quantity of fluid had been passed, it ceased altogether and urine began to pass through the urethra. The natural state of affairs gradually became established, but the patient became again very ill. The spasms reappeared, accompanied by headache, swelling of the feet, and great swelling of the face. These symptoms lasted about a week and then gradually disappeared, and the patient regained her usual health, which has continued until the present time. Dr. Rice naturally asks: "Was this vicarious urination? If so, how is it to be explained? Through what channel did it travel? The fluid certainly stood the tests for urine, and its elimination enabled the patient to live."

THE LIVERPOOL HEALTH COMMITTEE.

ALDERMAN E. H. COOKSON, the chairman of the Liverpool Health Committee, referred to the work of the department during the past year at the final meeting of the committee for the municipal year held on Oct. 20th. The sewers constructed during the year extended to 4⅜ miles; sewers reconstructed, 3⅜ miles; sewers constructed by builders and supervised by the sewerage department, 4½ miles; sewers, brooks, and culverts repaired, 1⅞ miles; sewers, brooks, and culverts cleansed, 13⅜ miles; sewers ventilated as constructed, 8⅞ miles; main sewers flushed, 289¼ miles; private house drains flushed (twice in the year), 3000 miles; deposits removed from sewers, 1038¾ loads, &c. Much benefit had already resulted from improved scavenging and the more liberal use of water for sanitary purposes. The remarkable connexion between filthy streets or a stinted water-supply and choleraic disease had been so frequently brought to the notice of the committee that there was no need to emphasise it further. By means of Parliamentary powers recently obtained they could deal more stringently with certain articles of food exposed for sale, and already the committee had put into practical operation the recommendation to test by examination the suitability of all candidates for the post of inspector of meat. They had also been granted power to close some of the city burial grounds which were found to be unwholesome. The recent Vaccination Act was referred to by the chairman in terms of strong condemnation. It could not be regarded without dismay by every sanitary authority in the country. Liverpool is, or was, one of the best vaccinated communities in the country—a result attained only after infinite care and pains by vaccination officers, guardians, and others. The consequence of this has been that Liverpool has been for many years practically free from those serious outbreaks of small-pox which attacked it periodically before vaccination was so thoroughly carried out. Exposed as Liverpool is to the importation of small-pox from almost every corner of the globe in which it may be prevalent, those responsible for the health of the city cannot but view with the greatest concern the Act which already in its brief existence has had the pernicious effect of raising the proportion of children who remain unvaccinated something like 50 per cent., and has added materially to the difficulty of those responsible for vaccination. The chairman went on to say that the permanent appointment of a bacteriologist was found to be a much more satisfactory arrangement than that which had hitherto prevailed of obtaining tests from time to time. Besides numerous researches into the conditions of food some careful investigations were set on foot into the sanitary aspect of the gas supplied to the city and to the consequences of the use of carburetted water-gas. With a view to ensure greater promptitude in dealing with infectious disease the committee have engaged a staff for the purpose of stripping the walls of apartments in which infection has occurred with very satisfactory results. It cannot be doubted that the sanitary work undertaken by the City Council during the ten years ending 1891 was less extensive than it would have been had not the Registrar-General's remarkable over-estimate of the population during that time misled the council. It is, however, fair to say that the Registrar-General applied to the municipal authorities for assistance in the revision of his estimate, but they did not respond to his suggestions. Returns involving an error of more than 20 per cent. were officially published by the Registrar-General during a great part of those ten years, and this had the effect of obscuring the necessity for sanitary work; and it was only at the census of this decade that the fallacy was exposed and the real need for more adequate sanitary measures became manifest. The excessive mortality of infants in some districts of the city is still a matter for much concern, being largely the result of unwholesome feeding. The general health of the city for the first six months of the year has been exceedingly satisfactory, the rate of mortality being 21·7, as against 22·0 per 1000 during the first six months of last year. During the three quarters zymotic disease has been kept well under control and shows a remarkable improvement on the preceding year, the numbers reported of the various forms of zymotic disease being upwards of 2000 less than last year, when the total number of cases was upwards of 6600. The diminution in the total number of cases of typhus fever, typhoid fever, and scarlet fever is no less than 53, 47, and 533 respectively.

THE LIBRARY OF THE BRISTOL MEDICO-CHIRURGICAL SOCIETY.

AT the annual meeting of this society, which was held on Oct. 12th, the honorary librarian, Mr. L. M. Griffiths, presented his report upon the condition of the library. It now consists of 7180 volumes, including 671 duplicates, and receives 170 periodicals. It also possesses busts of William Budd and James Syme. But this library is not the only medical library to which the medical men of Bristol have access. The Bristol Medical Library is made up of the libraries of the following bodies, which possess respectively books in the under-mentioned numbers: the Medico-Chirurgical Society, 7180 volumes; the Faculty of Medicine, 6539 volumes; the Royal Infirmary, 3650 volumes; and the General Hospital, 1381 volumes—a total for the conjoint libraries of 18,750 volumes and 204 current periodicals. The catalogue is now nearly complete—if, indeed, a library catalogue can ever be complete—and has been made easier for reference by the addition of a card catalogue. As the library of the Bristol Medico-Chirurgical Society only dates from 1891 it will be seen that the labours of the members and the librarian have been by no means in vain. Mr. Griffiths, in resigning his post, which he has held uninterruptedly since his election in 1891, referred to the fact that the conjoint library scheme demanded that the new librarian should be a man of many parts.

"No longer must he be one who has little more than a capacity for remembering the titles of the works under his care and an interest in the quantitative development of the library. Now he must be a scholar, acquainted with languages; a man of wide literary outlook, of comprehensive professional knowledge, of large bibliographical acquirements, gifted with the power of lucid exposition in order to make others realise the resources of their library and able to give demonstrations of the practical and historical nature of its grouped contents. In addition to all this, he must be prepared to give a large amount of time to the superintendence of the library and its correspondence, and able from his position to get in touch with librarians in all parts of the world and from his knowledge to judge with accuracy in what particular respect advantage to his library might be

Digitized by Google

best secured. Also, to know how to render help to readers who turn to him for assistance must not be lost sight of among other qualifications of the librarian, and even this must be exceeded if the library is to give its best to the profession, for he must be ready, even before he is asked, to point students to the avenues by which they can reach the goal they are seeking."

These are wise and weighty words. A good librarian is possibly like a poet—born and not made. Much can be done by training, but if the capacity is not there it cannot be inculcated. Mr. Griffiths has done such admirable work that we can only say we are sincerely sorry that he feels himself unable to continue in the position in which he has laboured so worthily.

ANOTHER ROMAN OCULISTS' SEAL.

AFTER a somewhat longer interval than usual intelligence comes of the discovery of another Roman oculists' seal. This time the relic has been disinterred in Germany, at Frankenthal, in the Rhine Valley. The seal has been described and edited by Dr. F. J. Hildenbrand and is of interest because the letters engraved upon it are in Greek as well as Roman characters and also because their interpretation presents many difficulties. The inscription which is upon the four edges of the seal is as follows: Λ.Α.Γ.Κ.Ο : Ο.Δ.Α.Κ : Λ.Τ.Μ.Ρ : Κ.Κ.Ο. The first three letters are probably initials concealing the name of the proprietor of the stamp. The final K.O. on the face of the seal denote either Kollyrium (or Krocodes) Opobalsamatum. If the K. is for Kollyrium then this is the second indication upon these documents of opobalsamatum as a remedy by itself. Upon one of these occasions the disease ad caliginem is given as the disease for which it was a remedy; that is to say, for defective vision. If the K. stands as initial for Krocodes, and we should therefore read Krocodes Opobalsamatum, then the text is unique, though we have a seal found in Bavaria which reads "Crocodes Diaopobalsamutum." The C.Δ. may stand for Crocodes Dialepedos (or Diamisus) and the A.K. for Ad Caliginem; but Dr. Hildenbrand thinks all the final letters of the four texts are initials of collyria and thinks the K. is for Krocodes. The P terminating line 3 is most likely a Collyrium, probably standing for Paccianum, Palladium, Penicillum, Pelagium, or Pyxinum. The final K.K.O. are almost certainly an abbreviated Kontra Kaliginem Oculorum. This leaves the Λ.Τ.Μ. unaccounted for. They may be short for Lippitudinem, for which Penicillum is often indicated as a remedy; or the M. may simply stand for Mixture, leaving the Λ.Τ. still a matter for conjecture. It is to be hoped that Capitaine Esperandieu will express his views soon upon the subject, as he is the greatest authority in this branch of research.

NERVE LESIONS IN BURNS.

AN article on this interesting subject appears in the *Archives de Physiologie* by Dr. Carlo Parascandolo. The causes of death after burns have been studied by many pathologists. It is well known that when death occurs in the course of an hour or two numerous visceral congestions are to be discovered. Curling and Erichsen noticed that the duodenum is the special seat of lesion, and that it becomes quickly inflamed and at a late period ulcerated, and Dupuytren, in summing up the conditions found after death from burns, attributed the greater part of the symptoms observed during life—as fever, vomiting, constipation, convulsions, hectic fever, and at a subsequent date diarrhœa—to gastro-intestinal irritation, the conditions varying with the date after the injury. When death was immediate after exposure to the flames there was considerable congestion of the intestinal mucous membrane with occasional hæmorrhages, and the same appearances were presented by the bronchial mucous membrane; sanguinolent fluid was also to be found in the arachnoid, pleura, pericardium, and peritoneum. After survival of some days the appearances of acute gastro-enteritis were visible, and at a still later period the intestinal tube was generally discoloured; there were red spots with or without ulceration and engorgement of the mesenteric ganglia. Dupuytren attributed these changes to sympathetic irritation. Later observers have found congestion of the brain and of the pons. Sir Samuel Wilks called attention to the frequency of purpuric spots on the pleuræ and in the cortical substance of the kidneys, and to fibrinous deposits in the veins, which he regarded as an indication of changes in the blood. Pneumonia is of common occurrence. Dr. Parascandolo experimented on dogs and rabbits and paid particular attention to the lesions of the nervous system occurring after burns of various degrees of severity. He found retraction of the grey matter of the cord with deformed posterior cornua and chromatolysis, both perinuclear and peripheric, in the cells; sometimes what he terms "homogeneisation of the protoplasm"; sometimes granular degeneration of chromatin with presence of chromatin rods in the nucleus; and sometimes total achromatolysis with destruction of the linin network. The protoplasmic processes presented varicose atrophy or lost their connexion with the cell body and were segmented—in fact, degeneration of the cord was the rule and this always affected the posterior cornua. The conclusions which he considers himself entitled to draw are that as the result of burns ptomaines make their appearance in the blood and in the muscles and other organs of animals suffering from them—a view which has been advanced by Dr. Parascandolo in a previous publication and which has been substantiated by researches which he made in conjunction with M. Ajello—and that the ptomaine thus produced is the cause of death after burns, as it brings about in the nervous centres anatomical changes which, however, are not *per se* capable of causing death. The alterations observable are similar to those met with in different types of infection. It is particularly worthy of notice that these ptomaines are capable when inoculated of producing in the nerve centres the same lesions as are observed in cases of burn.

"RETURN" CASES OF SCARLET FEVER.

CASES of this kind have been but little in evidence of late—a fact which may be due to two causes: greater care exercised in the discharge of patients from isolation hospitals and an appreciation on the part of the public that it is extremely difficult to prevent the occasional occurrence of such cases. We have discussed this question many times before and we have given due weight to that view of it which regards residual infection in the air and other passages of the body as one of the chief causes of these annoying manifestations. Dr. Niven of Manchester has, amongst others, devoted much attention to this subject and he has so modified the procedure at the Monsall Fever Hospital as to afford practical illustration of the importance of this aspect of the question. The method of dealing with the cases before discharge has been as follows: certain wooden pavilions were set apart as convalescent wards for scarlet fever cases, it being understood that no case was to be sent into these wards until six weeks had elapsed from the onset of the illness or until all signs of desquamation had disappeared. In the first instance only such cases as were free from discharges from any of the orifices, such as the nose or ears, were admitted, but it was found difficult to carry out this last particular. The convalescent children were encouraged freely to take exercise in the open air with a view to the oxidation of infective material and the dislodgement of infective particles. During the continuance of

Digitized by Google

this practice not one return case occurred in connexion with Manchester patients discharged from the convalescent wards. Such cases as did occur during 1897 occurred apparently when the necessary conditions as regards the convalescent wards were not being rigidly adhered to; and when there was much pressure on the accommodation the rigidity of the practice had of necessity to be relaxed. To carry out this form of additional isolation under stress is obviously impossible at the present time in most of our fever hospitals, and "return" cases must, we fear, be looked for from time to time. Still, efforts may be made in many places to carry out this plan, even although the circumstances will only admit of its partial application. It will be for the medical officers of fever hospitals to obtain, as far as is possible, sufficient convalescent hospital accommodation to enable complete isolation to be carried out. Doubtless, however, there are other sources of the so-called "return cases," and in spite of every precaution we must not be altogether surprised at the occurrence now and then of such cases.

THE ABUSE OF MEDICAL CHARITIES.

MEDICAL Missions, if properly conducted, serve a very useful purpose, but, like every other good thing, they are liable to abuse. An inquest was recently held by Mr. E. N. Wood, the deputy coroner for Bermondsey, upon the body of a child, aged two years, the daughter of a tinplate worker. The deceased child had attended at the Oxford Medical Mission in Abbey-street, but becoming worse Mr. J. H. Collymore was called in. The child, however, died from peritonitis. Mr. Collymore, in the course of the inquest, complained of the indiscriminate way in which cards of admission to the Mission were given out, without any regard to the circumstances of the recipients. The coroner coincided and remarked that it was quite time that hospital authorities took steps to prevent such abuse. In his opinion two-thirds of the patients who were treated at hospitals ought not to be treated there, for they were well able to pay. The jury also expressed the same opinions in delivering their verdict. Of course, we have said these things over and over again, but it is consoling to find a coroner's jury taking the same line as ourselves. We do not know what the status of the Oxford Medical Mission may be, for it does not appear in the Post Office Directory; but if it should be a reputable institution—and by its name it should be—we would counsel the authorities thereof to take more care in the distribution of their relief orders.

ANKYLOSIS OF THE SPINE, HIPS, AND SHOULDERS—"SPONDYLOSE RHIZOMÉLIQUE."

DR. PIERRE MARIE, who has earned so much distinction in describing new diseases of the skeleton, thus denominates a rare condition characterised by extreme rigidity of the spine and stiffness more or less complete of the hip- and shoulder-joints. A summary of his paper published in the *Revue de Médecine*, April, 1898, appears in a recent number of the *Revue des Sciences Médicales*. He has observed three cases and collected four. The stiffness of the spine is complete in the lower half; higher, especially in the cervical region, the column may preserve for some time a certain mobility. There is kyphosis due to a considerable and abrupt curvature of the cervical spine and a little to curvature of the superior dorsal spine. Hyperostoses are not limited to the inferior part of the spine, for osseous projections can be felt on the posterior wall of the pharynx. The hips are fixed in a position of flexion and adduction; the shoulders are much less affected. The movements of the knees are more or less limited, without true ankylosis. In two cases there were nodosities on the hands. The respiration is entirely diaphragmatic. All the cases occurred in adult males. They are too few for a general statement of the etiology and course of the disease, which, according to Dr. Marie, should be distinguished from chronic deforming rheumatism, from hereditary traumatic kyphosis, and from acromegalic deforming polyarthritis.

THE BRITISH RED CROSS SOCIETY.

THE secretary of the British Red Cross Society encloses to us for publication the following letter received from Surgeon-General W. Taylor, the principal medical officer with the forces in Egypt, to Lord Wantage, the chairman of the Council of the Society, which seems to us to be of sufficient interest for publication.

Cairo, Oct. 16th, 1898.

DEAR LORD WANTAGE,—Having come down in the *Mayflower* on her last trip from Assouan, I feel I cannot let a mail go out without writing to thank you, and through you the National Aid Society, for the great assistance given to the Army Medical Service, in bringing back the sick and wounded from the Soudan. I have written an official expression of my opinion of the great benefit and comfort the poor fellows, officers and soldiers, obtained by being saved from the trying railway journey from Assouan to Cairo. I have not a doubt that several lives were saved by that, and I am quite sure the convalescence of many was hastened and made safe by the comfortable, pleasant river trip. Colonel Young deserves all praise for the courteous and kind way in which he worked in harmony with the officers and men of the Royal Army Medical Corps. Personally, I feel very deeply indebted to you for the invaluable help given to the Medical Service in the way I have mentioned, and I beg you to accept my sincere thanks for having enabled me to transport such a number of the sick and all the wounded in such comfort.

I am, yours very truly,

W. TAYLOR.

FUNCTIONS OF THE OPTIC THALAMI.

THE October number of the *Archives de Physiologie* contains an article giving an account of some recent researches made by M. J. Sellier and M. H. Verger on the functions of the optic thalami. The deep position of the thalami renders them difficult of access and it is not surprising that differences of opinion in regard to their function should exist, and that whilst Fournié, Ferrier, and Lemoine came to the conclusion that there were sensory troubles after destruction of the optic thalami, Nothnagel failed to find any defect in the general sensibility of the body, but noticed that animals in which the thalami were destroyed on both sides seemed to have lost the sense of the position of their limbs, since without being paralysed they allowed them to remain in any position in which they were placed. M. Sellier and M. Verger determined to make some further researches with improved methods of investigation, with the object of ascertaining with greater exactness the effects of injury to this region of the brain. They selected the dog and adopted the plan of bipolar electrolysis, in which fine needles were made to penetrate the substance of the thalami and a current of a mean strength of 10 milliampères was passed. In none of these animals were any symptoms of meningitis observed, and the necropsy in each case showed that the destruction of tissue was small (of about the size of a grain of maize) and sharply defined. The animals were allowed to recover from the operation and tested systematically for some weeks. It was found when examined from eight to ten days after the operation that motility and sensitiveness to heat were always intact. The sense of the position of the limbs and the tactile sensibility were always manifestly affected. At the conclusion of a fortnight the disturbances of sensibility had entirely disappeared, which M. Sellier and M. Verger regard as the most important outcome of their observations. In two cases there were marked and permanent visual troubles, but they were unable to determine whether there was complete unilateral

Digitized by Google

blindness or a crossed hemianopsia. They satisfied themselves that the optic thalami have no influence on the voluntary movements of the animal operated on and that there were no compulsory or forced movements. Their sensory *rôle* is undeniable, but the thalamic anæsthesiæ, like cortical anæsthesiæ, do not include sensibility to pain and are transitory in duration—circumstances which support the view that the functions of the cerebral ganglia have similar if not identical functions to those of the convolutions of the brain.

THE POSITION OF COUNTY MEDICAL OFFICERS.

THE President of the Local Government Board gave notice in the last session of certain clauses which were to be inserted in a group of Water Bills before the House of Commons. The Executive Council of the County Councils' Association wish to have county councils and their medical officers placed in the same position in these clauses as that contemplated to be given to local sanitary authorities and medical officers of health with regard to water-supply. The fact that the medical officers to county councils were not to enjoy the same powers in regard to making analyses of water-supplies as the medical officers of health to sanitary authorities was probably an oversight which will be remedied when the clauses are introduced into the House.

REPORT OF THE CAPE OF GOOD HOPE VETERINARY DEPARTMENT FOR 1897.

THE Blue Book issued by the Department of Agriculture for the Cape of Good Hope is especially interesting this year on account of the recent trouble which there has been with rinderpest amongst the cattle. The report contains a full account of the work which has been done by the chief colonial veterinary surgeon, Mr. D. Hutcheon, and his assistants. At the beginning of 1897 the veterinary staff was increased to 28 men, but even with this number some districts had to be neglected or supplied with unqualified men specially instructed in the work of inoculation. It is interesting to note, at a time when the relations between the English and Dutch residents are often somewhat strained, that "the most urgent demands for veterinary surgeons came from the districts in which the farmers are principally Dutch, who as a rule do not professedly estimate the services of these officers very highly"; and again, "when inoculation had practically ceased in many districts the local committees and farmers strongly protested against the veterinary surgeons being removed, as cases of rinderpest continued to reappear." The report gives a complete history of the course of the disease from its commencement to the present time, particular stress being laid upon the various methods carried out for preventive and curative treatment and the results attained. Dr. Koch's suggestion of injection with the bile of diseased animals and Dr. Edington's modification of glycerinated bile were each tried extensively, as was also the inoculation with serum obtained from animals which had recovered from a severe attack of rinderpest spontaneously contracted. The results of each are given, those of the serum treatment appearing to come out the best, particularly with regard to the length of time during which immunity could be obtained. One point especially noticed was that, "although all the cattle are given the disease in a more or less modified form by the application of the serum treatment, it is a curious fact that infection is rarely carried from such a herd if ordinary quarantine precautions are taken," whereas in several of the reports reference is made to the fact that the disease was introduced into districts which had up to then been free by the use of the bile inoculation intended to confer immunity. Mr. Hutcheon speaks very highly of the serum treatment and says, in concluding his report upon it: "It is too early to generalise on the subject, but I entertain hopes that by means of serum inoculation systematically applied the disease may be eradicated from the country." The second part of the report is devoted to the accounts sent in by each of the assistant veterinary surgeons, almost all of whom speak much more favourably of the serum treatment than of any other used. Considering the enormous amount of work which had to be done and the almost insuperable obstacles and difficulties which had to be overcome it must be admitted that the work performed by the Veterinary Department of the Cape Board of Agriculture has been very satisfactory, and that a great deal has been added to our knowledge of the treatment of rinderpest and diseases of a similar nature. In fact, it is quite apparent that more has been discovered with regard to this disease during the past twelve months than during the many hundreds of years in which we know it has existed. An interesting paper by Mr. Maberly dealing with the subject will be found at p. 1189 of our present issue.

PHYSICAL EDUCATION IN ITALY.

UNDER the auspices of the Minister of Public Instruction the following programme of athletic sports was recently carried out at Turin, the competitors being pupils of the various educational institutions throughout the country. 1. Speed: 165 yards in a straight line over the flat and without obstacles. 2. Endurance and speed: about 6 miles on the flat. 3. Swimming: 110 yards with the current. 4. Rolling or throwing the discus. This contest consisted of two parts. In the first the discus was rolled as far as possible on the flat; in the second it was thrown through the air, the distance being measured to the spot where it first alighted. 5. Pitching an iron quoit weighing 22 lb. 6. Casting a javelin weighing about 3 lb. at a rectangular target 5 ft. high and 3 ft. broad. The distance of the target from the casting-point is not stated. 7. Pole-leaping with the help of a spring-board, the leapers to begin at 7 ft. 8. Competitive gymnastic exercises of various kinds, including horizontal bar, parallel bar, vaulting horse, and trapeze rings. In addition to the foregoing teams of students numbering at least eight besides their captains took part in sundry games, among them being Association football, hockey, lacrosse, battledore, and lawn-tennis. In conclusion, prizes consisting of medals and diplomas were freely distributed amongst the victors.

THE LONDON WATER-SUPPLY.

LAST week we announced that the London County Council would at its meeting on Nov. 1st consider a report recently presented by the Water Committee. There was a question at the outset as to whether the Council would at once formulate its proposals and lay them before Parliament in the coming session or whether it would wait for the report of the Royal Commission. The former course was very definitely decided upon at the last meeting and the County Council's attitude on the whole question has now been unmistakeably defined. All the recommendations of the Water Committee were adopted. Upon two recommendations only, indeed, out of eight in all, did the Council go to a division. The first was that in which Mr. Dickinson moved that a Bill be promoted in the coming session of Parliament for the purchase by the Council of the undertakings of the eight metropolitan water companies by agreement or failing agreement by compulsion. To this Lord Onslow moved an amendment to the effect that it would be futile for the Council to lay down any policy until the views of the Royal Commission were known. The amendment was rejected by 101 to 15, a result which must not be regarded as a big Progressive

Digitized by Google

victory. so much as a sequel to the breakdown of the supply in the East-end of London. Our opinion expressed some months ago that the continued existence of a limited supply of water to the East-end of London would direct public opinion more forcibly than ever to the entire question of future administration and requirements with a view to speedy and satisfactory settlement is thus confirmed. The recommendation of the Water Committee that a Bill should be promoted in the coming session of Parliament for the purpose of empowering the Council to bring an additional supply of water to London from Wales was approved unanimously, as were the various recommendations dealing with the administrative area and the questions of arbitration and acquirement. Lastly, the recommendation that the Bill should contain provisions authorising the Council to proceed forthwith with the connecting and laying of mains and other works necessary in order to enable it to protect any part of the metropolis from want of water was adopted, a contrary amendment moved by Mr. Beachcroft being rejected by 70 to 28.

DEATH UNDER CHLOROFORM.

A DEATH under chloroform took place at the Victoria Hospital, Lewes, on Oct. 1st. We are indebted to Mr. Wilson, the house surgeon, for careful notes of the occurrence. The patient, a child, aged four years, was suffering from lumbar abscess connected with disease of the spine. Chloroform was administered from a modification of Skinner's mask (Schimmelbusch). The child breathed deeply at first, but the respiration then became gasping and finally ceased, and although the usual methods for resuscitation were applied the little patient did not recover. Heart movements were observed after respiration had completely ceased. The death was no doubt due, as Mr. Wilson points out, to paralysis of the respiratory centre through an excessive intake of chloroform at the commencement of the administration—a fact which is commonly overlooked by those who advise the use of Skinner's mask and like apparatus. By their use it is very difficult to counteract the irregularity of the patient's breathing and to lessen the dose during deep respiration. In theory it may be said that a careful anæsthetist will remove the mask when any alteration in respiration takes place, but in practice this can seldom be done, especially in the case of young children, who until they are fully anæsthetised rarely present the same rhythm of respiration for many seconds together. Of course, with a drop bottle more can be done to regulate the dose.

THE ROYAL COMMISSION ON SEWAGE DISPOSAL.

THE length of time which the recently-appointed Royal Commission on Sewage Disposal must inevitably occupy if the inquiry is to be at all comprehensive threatens to prove a serious obstacle in the way of progressive sanitation. The appointment of the Commission, in fact, has placed the whole question *sub judice*, and many local authorities whose duty it is to carry out in the meantime a system of sewage and refuse disposal in our towns and villages are inclined to wait until the Commission pronounce judgment upon the merits or demerits of the processes in vogue. Lord Iddesleigh recently addressed a letter to the papers in which he stated that the Commission would view with the gravest concern any postponement on the part of the local authorities of the carrying out of works for the purification of trade refuse and sewage until the Commission have issued their report. But what, we ask, are the local authorities in the meantime to do? They may well hesitate to construct work and spend money on a method with the risk that in two years' time, when the report is issued, the whole scheme may be condemned and a perfectly new departure insisted upon. Further, it appears that the Local Government Board now refuse to sanction a loan for the purpose of carrying on disposal works unless the process is recommended in the report of the Royal Commission now sitting, and how can this possibly be known? This refusal is obviously inconsistent with the expression of grave concern contained in Lord Iddesleigh's letter as to the postponement of the carrying out of refuse and sewage disposal works until the views of the Commission are known. The Local Government Board must, it seems to us, meet these cases in some way or other or a standstill in the sanitary affairs of the country may happen which might have very serious consequences.

THE USE OF MORPHIA IN BRIGHT'S DISEASE.

IN 1873 in the *New York Medical Record* Dr. Loomis stated that he had treated uræmic convulsions by the hypodermic administration of morphia with marked success; in THE LANCET of August 3rd and 10th, 1889, Dr. Stephen Mackenzie confirmed his conclusions. At the recent annual meeting of the American Medical Association Dr. Sydney Ringer of London read a paper on this subject, "The Use of Morphia in Bright's Disease," which was published in the Journal of the Association on Oct. 8th. Dr. Osler writes concerning uræmia: "For the restlessness and delirium morphia is indispensable. Since its recommendation by Stephen Mackenzie I have used this remedy extensively and can speak of its great value in these cases. I have never seen ill effects or tendency to coma follow." Dr. Ringer entirely confirms these statements. He finds that morphia hypodermically employed is of conspicuous benefit in uræmic dyspnœa and in uræmic asthma. But of course dyspnœa due to dropsy of the lung or fluid in the chest is not benefited. Also, the headache and sleeplessness of uræmic patients can generally be removed. Dr. Ringer has not employed this treatment in uræmic convulsions or coma, but has largely used it for other uræmic troubles, and is certain that it may be employed in these cases without risk and with every prospect of benefit.

THE INCREASE IN WEIGHT WHICH SOMETIMES PRECEDES DEATH IN VERY YOUNG INFANTS.

AT the present time, when the systematic weighing of new-born infants is regarded as an important feature in their management and when we are accustomed to look upon a steady increase in weight as an indication of their general well-being, it is a little startling to find that such an increase without any corresponding improvement in their general condition occurring in cases where the weight has previously been diminishing or stationary may be the first indication of impending, often rapid, and even in some cases of sudden death. Such is the conclusion that Dr. G. Durante draws in a paper upon the subject in the September number of the *Annals of Gynæcology*. As he points out, the oscillations in the weight of a new-born infant correspond fairly accurately to its general condition. Any loss of weight is as a rule proportional to the gravity of the condition causing it and usually persists until the time of death, while approaching convalescence is in most cases indicated by an increase in the weight of the child. But there are exceptions to this general rule, and Dr. Durante finds that an increase in weight sometimes occurs in the two or three days preceding death. Such an increase was observed by him in 11 out of 130 fatal cases. In some of these cases death followed a steady rise in the weight without any preceding fall or stationary period. Such cases are, however, rare. More commonly after a long stationary period a sudden increase occurred without any improvement in the general

Digitized by Google

condition, and the child died just at the time when he or she appeared from the weight to be gaining ground a little. In other cases after a more or less pronounced loss the weight rose suddenly and death ensued. The gain in weight varies from 50 to 75 grammes in from two to four days, but it may reach as much as 200 or 350 grammes in from five to six days, the increase, unaccompanied as it is by any appreciable improvement in the general health, contrasting strangely with the preceding loss or stationary period. Of the 11 cases observed 1 died with a suppurating sore on the leg, 1 from general tuberculosis, 2 were syphilitic, in 5 the only lesion present was marked fatty degeneration of the liver, while in 1 the thymus was hypertrophied and in another no cause for the fatal result could be found at the necropsy. Dr. Durante appears to have taken adequate means to exclude any possible sources of error. The children had been some time under observation and the increase was not due to constipation or to any increase in the amount of food administered. It is impossible to draw any definite conclusion as to the cause of this increase of weight from such a small number of cases. The observations are, however, of practical interest. The weight of new-born infants often fluctuates from day to day in a most surprising manner, yet the fact that an increase in weight unaccompanied by any definite improvement in the child's general condition is followed at times by a rapidly fatal result may be of value in certain cases in enabling a more accurate prognosis to be made. Further observations upon this subject are, however, required before its constancy or exact clinical value can be determined.

THE Harben Lectures of the Royal Institute of Public Health for 1898 by Sir Richard Thorne Thorne, K.C.B., M.B. Lond., F.R.S., commenced on Wednesday, Nov. 2nd, and will be continued on Nov. 9th, and 16th, at 5 P.M., in the Examination Hall of the Royal Colleges of Physicians and Surgeons, Victoria-embankment. The subject chosen is "The Administrative Control of Tuberculosis."

THE following figures reached us too late for insertion in the table giving the entries at the medical schools which we published last week. At Cambridge University 40 students have joined preliminary scientific classes with a view to graduating in medicine. At the London School of Dental Surgery, Leicester-square, 39 students have entered.

THE annual dinner of the Irish Medical Schools' and Graduates' Association will be held on Nov. 23rd at 7.15 at the Café Monico, as we have already announced. Members desirous of being present are requested to communicate with Mr. P. J. Freyer, 46, Harley-street, W.

THE Morison Lectures of the Royal College of Physicians of Edinburgh will be delivered in the College Hall, 9, Queen-street, by Dr. Alexander Morison, at 5 P.M., on Monday, Nov. 7th, Wednesday, Nov. 9th, and Friday, Nov. 11th.

THE annual dinner of the Aberdeen University Club will be held in the Venetian Saloon of the Holborn Restaurant on Wednesday, Nov. 16th, at 7 P.M., under the presidency of Lord Strathcona and Mount Royal.

IN the district of Iskander, in the Samarcand territory of Russia, there have been some cases of plague. The Russian Government are taking precautions against the spread of the disease.

THE Queen Regent of Spain has created Mr. Charles Lane Sansom, F.R.C.S. Edin., a Knight of the Order of Isabella.

A native officer, Tasildar Sundarasa Iyer, while on plague duty, has been stoned to death at Hindupur.

AN INTERNATIONAL MONUMENT TO HANS WILHELM MEYER.

THE inauguration of the monument to Wilhelm Meyer took place at Copenhagen on Oct. 25th, the birthday of the deceased, at 2 P.M. Among those present at the inauguration were the widow and other relatives of the late Dr. Meyer, the Mayor of Copenhagen, representatives of the Municipality and University of Copenhagen, the members of the Danish Committee, Sir Felix Semon from England, Dr. Edmund Meyer, the treasurer of the German Committee, from Berlin, the sculptor, Professor Bissen, and a large assembly, consisting chiefly of medical men and patients of the deceased. The ceremony commenced with the singing of a cantata by the Danish poet, Ernst von der Reck, which was sung by medical students. Sir Felix Semon, who had been requested by the Executive Committee of the Wilhelm Meyer Memorial to make the inaugural speech and to hand over the monument, erected by international subscriptions, to the care of the Municipality of Copenhagen, thereupon made the following speech:—

MR. MAYOR, LADIES, AND GENTLEMEN,—The Executive Committee of the Wilhelm Meyer Memorial have delegated to me the signal honour to hand over the monument, erected by international subscriptions to his honour, to the care of the Copenhagen municipality. In fulfilling this pleasing task I much regret my inability to address you in the Danish tongue, and for this reason alone I must not trespass long upon your patience. At the same time this occasion is such a very unusual one that I may be permitted to say a few words pointing out its meaning and importance. We are assembled here to-day to unveil a monument erected in honour of the late Dr. Hans Wilhelm Meyer. A monument in honour of a physician—that in itself is a very uncommon thing. To be immortalised by the sculptor's art in bronze or marble in a public place has usually been reserved from times of old to some few classes of the community only. Great rulers, benevolent or warrior princes, distinguished statesmen, victorious generals and admirals—these are the privileged mortals in honour of whom most frequently monuments have been erected; more rarely has such a reward fallen to the lot of great artists, poets, painters, musicians, and sculptors; still less frequently have men of science, philosophers, law-givers, inventors, and other leaders of intellect thus been distinguished; few and far between are monuments erected in honour of members of the medical profession. Nor is the reason of this far to seek. Slowly and by the labour of many is the edifice of scientific medicine being erected. The brain work of a lifetime of a physician usually means hardly a single brick in this ever-growing structure. Even if of uncommon importance his achievements rarely pass outside a comparatively narrow circle within his own profession; not often is his fame of a really universal character amongst his own compeers; still less frequently does it appeal to the imagination, to the gratitude of the community at large. Thus the ordinary fate of the scientific physician, even if in his day he has been successful in promoting by teaching and writing the welfare of mankind, as a rule is not of a largely resplendent character. A few complimentary obituary notices, the grateful recollection of some friends and pupils, not as a rule lasting longer than into the immediately following generation, finally a resting place for his name in those corners of medical literature in the development of which he has been most active,—this is the summary of the life-work of most leaders of the medical profession. What, then, has been the conspicuous merit of Hans Wilhelm Meyer that he should have been singled out for so unusual an honour as the one which is going to be paid to his memory to-day? The answer is easily given. It is now just thirty-one years since he was one day consulted by a girl, aged twenty years, who suffered from deafness, whose voice was most peculiar, and the expression of whose face was almost idiotic. Treatment directed to the ears and to the throat failed, and it was not until the puzzled observer one day introduced his finger into the space between the nose and throat that an unexpected solution was met with. Instead of penetrating into an open cavity the finger was arrested by a large, soft, easily bleeding mass, a condition the existence and nature of which in those days formed a *terra incognita*.

AN INTERNATIONAL MONUMENT TO HANS WILHELM MEYER.

The Monument to Hans Wilhelm Meyer, executed by Runeberg and Bissen, erected in Copenhagen by international subscription, and unveiled on Oct. 25th, 1898.

Digitized by Google

Digitized by Google

Meyer succeeded in removing this mass by operation, with the result that the deafness was materially improved, the voice became natural, and the idiotic expression of the face disappeared. Gratifying as this result was in itself it was, however, only then that Meyer's real merit commenced. Schopenhauer has truly said that not he is finder of a thing who lifts it from the ground and drops it again, but he who takes it up and recognising its value keeps it. If Meyer had regarded his experience in the light of a mere pathological curiosity, again years and years might have passed before the importance of the subject was realised. But with the true instinct of the scientific observer who develops what is ultimately to become an important truth from small beginnings Meyer did not drop the clue which a casual observation had placed in his hands. He began studying the subject in all its bearings; he examined the masses he had removed with regard to their structure, and finding them to be glandular in character gave them the name of "adenoid vegetations"; he investigated the results which obstruction of the space between the nose and throat exercises upon respiration hearing, articulation, facial expression, and general mental and bodily development; he examined 2000 Copenhagen schoolchildren with regard to the frequency of this affection; he made himself the apostle of his own teaching by proclaiming it, not only in his own country, but also in scientific publications abroad. In one word, to such an extent did he realise the true significance of his discovery that he left to his successors merely the addition of more or less important details, whilst the foundation of the edifice erected by him has remained unchanged from the time of his own first publication on the subject. Nevertheless it cannot be said that this teaching at first made very rapid headway. When in 1881 he introduced a discussion on the subject at the International Medical Congress of London it came almost—I well remember—as a novelty to many of his audience, although that was mainly composed of specialists, and it was only in the next decade that the true importance of the subject was realised throughout the world. It was at first not easy to convince the bulk of the medical profession, the parents of the mostly juvenile patients, and the schoolmasters that a discovery had been made which, like few others in medicine, was of the utmost practical importance concerning the development of a healthy mind in a healthy body of the rising generation, and it needed the irrefutable proof of the surprising improvement seen in the subjects of successful operations to make this conviction a universal one. But truth, though slowly, ever forces its onward way, and when Meyer three years ago closed his eyes he had the satisfaction of knowing that the value of his discovery had at last been universally recognised. Already then the number of those who through the timely removal of the obstructing glands had been saved from lifelong deafness or from the lasting results of obstructed nasal respiration amounted to many thousands, and the benefits achieved through Meyer's merits will continue to accrue in future times to hundreds of thousands and to millions. The proposition made immediately after his death to erect a statue to him at Copenhagen under these circumstances met with the most sympathetic reception; committees were formed in almost every country in which scientific medicine is established; in Great Britain the movement was particularly favoured by the patronage which Her Royal Highness the Princess of Wales, herself a daughter of the Royal Danish House, most graciously extended to it; physicians, surgeons, specialists, general practitioners, grateful patients, and former patients showed themselves anxious to contribute their mite towards a truly international monument of gratitude of his contemporaries towards the deceased great benefactor of the human race, and the result we see to-day before us in the shape of this beautiful and touching monument, which will carry the names of the artists, Messrs. Bissen and Runeberg, to every quarter of the globe. It is true that in the general chorus of approbation a few dissentient voices have been heard. "What, after all," it has been said, "has been Meyer's extraordinary merit? He put his finger up behind a patient's palate and found an obstruction, which he removed, and which turned out to occur more frequently than could at first have been supposed." Very true; but need I remind my audience that the same specious argument has been used against the claims of Christopher Columbus? America had been there all the time, only waiting, as it were, for the bold sailor who dared to go westwards until he struck a new continent. But Columbus did it. The naso-pharyngeal cavity had been there waiting for its explorer ever since man in his present shape has been in existence; pathological obstruction of this cavity has been as old as the records of the sculptor's art allow us to go back. In the last paper on the subject, which Meyer wrote a few months before his death, he showed that the facial expression of some Greek statues and busts which have come down to our times left no doubt that the originals had been suffering from "adenoid vegetations"; mediæval portraits of historical personages prove the same fact. Any physician might have conceived the idea of investigating the subject as Meyer did in 1868, but it was left to Meyer to do it, and having done so to realise the importance of his discovery whereby he became without exaggeration a true benefactor of the human race. That is why we are assembled here to-day; that is why we do honour to his memory. Gentlemen, the country of Denmark has been rich in producing men of eminence in almost all branches of human activity. If in many instances the nature of their distinction is better known to their own compatriots than to the world at large this is but natural and is an experience which is repeated in every country under the sun. There are some Danes, however, whose names are household words throughout the civilised world, whose reputation is not a local but a universal one, and who, whilst their countrymen may be justly proud of them, belong, as it were, to mankind at large. Need I mention the names of Tycho Brahe, of Bertel Thorwaldsen, of Hans Christian Oersted, of Hans Christian Andersen, and of Niels Gade? To those great names I think may be reverently added the name of Hans Wilhelm Meyer, one of the greatest benefactors to mankind medicine has known. Mr. Mayor, in the name of the subscribers to this monument, who have gladly contributed towards this external sign of gratitude erected in memory of your great compatriot, I have the honour to deliver the monument of Hans Wilhelm Meyer to the safe keeping of the municipality of Copenhagen.

Towards the end of Sir Felix Semon's speech the veil was withdrawn and the monument exposed to public view. It is considered one of the finest monuments in Copenhagen and loses nothing by its site, one of the new boulevards close to the Deaf and Dumb Asylum. The monument itself consists of a bronze bust of Hans Wilhelm Meyer on an oblong pedestal of polished brown granite with the following inscription:—

In front.	*On back.*
Laegen HANS WILHELM MEYER. * Fredericia, 25 Oktob., 1824. * Venetzia, 3 Juni, 1895.	Dette Mindesmaerke reistes i Aaret 1898 ved Bidrag fra Danmark og Udlandet. (This monument has been erected by contributions from Denmark and foreign countries.)

On the pedestal are written the names of those countries which have subscribed to the monument: "Australia, Austria, Batavia, Belgica, Britannia, Civitates fœderatæ Americanæ septentrionales, Dania, Gallia, Germania, Helvetia, Hispania, Hungaria, Italia, Norvegia, Polonia, Russia." The pedestal rests on several steps of roughly-hewn granite, mounting which is seen a most beautiful female figure (bronze), more than life-size, representing the Goddess of Medicine, who whilst she rests her left hand upon the staff of Æsculapius with her right offers the palm of glory to Dr. Meyer. The beautiful monument does full justice to the genius of the Finnish sculptor Runeberg, who made the bust of Meyer, and of the Danish sculptor Professor Bissen, who designed the female figure.

The MAYOR of COPENHAGEN thanked Sir Felix Semon in the following speech: Sir Felix Semon has just inaugurated and unveiled this monument and presented it to the municipality of Copenhagen. As a member of the municipality I have been commissioned to accept this beautiful monument, due to the united energies of the sculptors Runeberg and Bissen, which has been erected in honour of the renowned Danish physician, Dr. Hans Wilhelm Meyer. His great discovery on the subject of ear and throat disease has been generally acknowledged amongst his colleagues, not only in his own country, but, as we have just heard from Sir Felix Semon, perhaps even more so far beyond its boundaries, and the monument is a proof in itself. It may well be said that the proof of the value of a medical discovery lies in its practical use in curing disease, and in this respect Dr. Meyer's discovery has stood its ground, for the method he discovered and indicated has cured many people, or at any rate relieved their sufferings. Dr. Meyer's method has been followed and

Digitized by Google

perhaps improved upon by many medical men at home and abroad—several of the most prominent of these we have the honour to see here amongst us—and we hope that their energetic work may succeed in still further perfecting what Dr. Meyer had begun; but one thing I think is certain, that not only now but also in the far future laryngologists and otologists will look up to Dr. Meyer as the pioneer and their master in this question, the man with the clear brain who saw and explained the connexion of causalities. This place which the Danish Committee and the municipality have chosen is, we may also say, in a state of development, but in a short time it will be one of the finest parts of our city, so that the beautiful monument will be even better placed than at present. With these few words, in the name of the municipality of Copenhagen I accept this monument in memorial of Dr. Hans Wilhelm Meyer and promise to keep it and guard it.

Dr. E. SCHMIEGELOW, the President of the International Executive Committee, added his thanks to those of the Mayor and more especially expressed the gratitude felt by the committee towards the Danish and foreign subscribers. As chairman of the original Danish committee he assured Sir Felix Semon that his countrymen were fully alive to the great and unusual compliment paid by the entire world to Danish medical science, and, indeed, to the whole Danish people, in the person of so worthy a representative as Hans Wilhelm Meyer had been.

In the afternoon Dr. E. Schmiegelow gave a dinner to the foreign representatives, the members of the committee, and many of the leading men in Danish medical science; and amongst those present were the Mayor of Copenhagen and the sculptor, Professor Bissen. Letters and telegrams were received from the Dutch Oto-laryngological Society and the Medical Society of Amsterdam (Professor Guye, Dr. Voute, and Dr. Burger); Norway (Professor Uchermann); Belgium (Dr. Delie); England (Dr. Cresswell Baber); America (Dr. Bryson Delavan); and others.

THE NEW OPERATING THEATRE AT SWANSEA HOSPITAL.

SIR WILLIAM MAC CORMAC, President of the Royal College of Surgeons of England, visited Swansea on Oct. 28th for the double purpose of opening the new operating theatre at the hospital and delivering an address at the annual meeting of the Swansea Medical Society. A large company assembled at the hospital about 3 P.M. and were received by the Mayor, Mr. Aeron Thomas, who in a short speech welcomed Sir William Mac Cormac to the town. Mr. Howel Watkins, speaking on behalf of the board of management of the hospital, said that for the new theatre the town was indebted to the public spirit and generosity of Mr. Benjamin Evans, J.P., who had defrayed the expense of putting up an entirely new building for the purpose. Sir William Mac Cormac, having opened the theatre with a gold key presented to him by Mrs. Benjamin Evans, expressed his admiration of what Mr. Evans had done for the institution and made an allusion to the assistance which had been rendered by the energy and knowledge of his old friend and pupil, Mr. W. F. Brook, senior surgeon to the hospital. A vote of thanks to Mr. and Mrs. Evans for their munificence having been proposed by Sir John Llewelyn, M.P., and seconded by Mr. Ebenezer Davies, Mr. Evans replied in a genial speech, thanking Sir William Mac Cormac for being present, eulogising the hospital staff, and describing various recent improvements as an evidence of the progressive spirit of the town. Sir William Mac Cormac also read a paper on the Past and Future of Surgery before the Swansea Medical Society, and the same evening he was present at the society's annual banquet, on which occasion Dr. T. D. Griffiths presided, the other speakers including Chancellor Smith, General Sir James Hills-Johns, the Mayor, and Sir John Llewelyn, M.P.

The operating theatre is an annexe approached from the lower corridor of the hospital and is built of polled stone with dressings of Bath stone. The plan consists of two half-circles with a radius of 11 ft., separated by an interval of 4 ft., thus measuring 26 ft. by 22 ft. It is lighted from a dome-shaped roof 20 ft. high in the centre by two top-lights, one of which is continuous with the main side-light, a slab of plate glass 8 ft. wide extending to a level of 3 ft. from the floor. The walls are lined throughout with Parian cement, glazed with "Blundell's petrifying fluid." The floor is terrazzo and on either side of the north side-light is raised into two tiers of high steps, each step carrying an iron rail. Thus solid masonry takes the place of the wooden and iron stands usually provided for spectators. The theatre is heated by two sets of low-pressure steam radiators standing in recesses swinging on hinges and situated in front of four air inlets. The latter are provided with closely fitting metal boxes, with fronts and backs of wire gauze enclosing cotton wool, by filtering through which all air entering the theatre is cleared of dust. In the wall at a height of 14 ft. is an extracting fan driven by a jet of water $\frac{1}{16}$ in. in diameter capable of displacing 1000 cubic feet of air per minute and set in motion by turning a tap. A shallow recess in the wall with embedded glass shelves closed in by glass and enamelled iron doors forms the instrument cupboard. Immediately behind it is the flue of one of the anæsthetising rooms, the heat from which prevents condensation of moisture within the cupboard. The theatre is entered through either of two anæsthetising rooms, each 12 ft. by 10 ft., which are floored and lined in a similar way. The work was carried out by Messrs. Wilson and Moxham, architects, from designs prepared by the surgeons of the hospital.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

A MEETING of the Comitia was held on Thursday, Oct. 27th, Sir SAMUEL WILKS, Bart., President, being in the chair.

The following gentlemen were admitted as Members: R. H. Crowley, M.D.Lond.; W. J. Fenton, M.B.Cantab.; and C. H. J. Lockyer, M.B. Lond. Licences were granted to 120 gentlemen who had passed the required examinations.

The PRESIDENT made some remarks in regard to his duties outside the College, drawing especial attention to the award of the Gilbert-Blane Prize for naval surgeons, the candidates for which had done much useful work; and to the position of the President as one of the trustees for the British Museum and the Tancred Scholarship. Sir Samuel Wilks also referred in glowing terms to the opening of the new medical laboratories at Liverpool. He considered that day to form the inauguration of a new system in medical teaching, the practical taking the place of the theoretical. He also announced that the Gilbert-Blane Prize had been awarded to Francis Clay, M.B., C.M. Edin., surgeon to H.M.S. *Thrush*, and to Percy Bassett Smith, M.B., C.M., staff-surgeon to H.M.S. *Magdala*. The Jenks Scholarship had been gained by Mr. William Hardy Fleetwood.

Communications were received, amongst others, from: 1. The Right Hon. A. J. Balfour and others, acknowledging the receipt of the declaration of the College respecting vaccination. 2. The Charity Commissioners, in reply to the College respecting a scheme for the maintenance of the Chelsea Physic Garden. A committee was appointed to consider the scheme, consisting of Dr. Hensley, Dr. Lauder Brunton, and Dr. Allchin. 3. The London County Council, asking the guidance of the college in the matter of the Notification of Infectious Puerperal Diseases. The following were nominated as a committee to consider the matter of nomenclature, with power to answer the letter:—Sir J. Williams, Dr. Payne, Dr. Champneys, Dr. Cullingworth, and Mr. Clayton. 4. The Society of Arts, respecting the award of the Swiney Prize to be made in January next. The President, Treasurer, Registrar, and Senior Censor, and Dr. Pavy were nominated as representatives of the College. 5. Mr. Trimmer, secretary of the Royal College of Surgeons of England, reporting certain proceedings of the Council of that body on August 2nd. 6. The Secretary of State for the Colonies, asking the present opinion of the College on the communicability of leprosy, in view of the report of the Berlin Conference (1897). The following were requested to act as a Committee to answer the communication: Sir Dyce Duckworth, Dr. R. Liveing, Dr. Heron, Dr. Payne, Dr. Head, and Dr. John Anderson. 7. The Seamen's Hospital Society, asking the College to nominate a representative on a committee appointed to organise a School of Tropical

Digitized by Google

Medicine in connexion with their branch hospital. Dr. Curnow explained that although Dr. Anderson and himself were physicians to the Seamen's Hospital at Greenwich they had not been consulted in the matter and, having detailed some of the correspondence which had taken place between himself and the secretary of the hospital, he moved "the previous question." Dr. Anderson having made a few remarks this was carried.

The audited accounts for the year ending Sept. 29th last were laid before the College. The quarterly report of the finance committee was received.

It was announced that the first award of the Bisset Hawkins Memorial would be made in July next and the medal would be presented on the St. Luke's Day following. A cast of the medal was handed round for the inspection of the Fellows.

Dr. Frederick Taylor was elected a member of the committee of management in place of Dr. Ord.

Reports were received from the committee of management and the laboratory committee, and Dr. Pye-Smith was re-elected a member of the latter.

After some further routine business the President dissolved the Comitia.

THE OUTBREAK OF PLAGUE IN VIENNA.

THE unfortunate Nurse Pecha died early on Sunday morning last from plague. She was a young, strong, healthy girl, and fought hard for her life, but eventually succumbed in spite of frequent injections of serum.

The disease has not spread at all thanks to the drastic precautionary measures which have been taken, and the city of Vienna, which last week was ripe for a panic, has now resumed its tranquillity. Nurse Hochegger, the other nurse who was ill, is pronounced out of danger.

The American Consul at Hamburg has received instructions that in consequence of the cases of plague in Vienna the American Government require 15 days' quarantine of all steerage passengers coming from that city, and already a large number of Austrian passengers have been prevented from joining one of the mail steamships.

Our Rome correspondent writes under date Nov. 1st: "Dr. Alessandro Lustig, who holds the chair of general pathology in the Florentine Istituto di Studi Superiori and directs the pathological laboratory in the same school, has just received from the Permanent Sanitary Commission of Vienna the cordial thanks of that body for his spontaneous offer of a supply of his *siero antipestifero*. The Commission adds that it will at once avail itself of the offer should the serum already furnished it from other quarters prove insufficient. At present it has on hand a supply from the Pasteur Institute of Paris."

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN thirty-three of the largest English towns 6752 births and 3844 deaths were registered during the week ending Oct. 29th. The annual rate of mortality in these towns, which had declined in the seven preceding weeks from 24·6 to 18·8 per 1000, further fell last week to 17·9. In London the rate was 16·3 per 1000, while it averaged 18·9 in the thirty-two provincial towns. The lowest death-rates in these towns were 9·6 in Croydon, 12·7 in Huddersfield, 12·9 in West Ham, and 13·5 in Halifax; the highest rates were 23·5 in Manchester, 24·3 in Blackburn, 24·9 in Wolverhampton, and 26·6 in Liverpool. The 3844 deaths in these towns included 455 which were referred to the principal zymotic diseases, against 618 and 538 in the two preceding weeks; of these, 152 resulted from diarrhœa, 84 from "fever" (principally enteric), 82 from diphtheria, 65 from measles, 38 from scarlet fever, and 34 from whooping-cough. The lowest death-rates from these diseases were recorded in Huddersfield, Derby, Halifax, Bradford, and Oldham; and the highest rates in West Ham, Bolton, Salford, and Sunderland. The greatest mortality from measles occurred in Portsmouth, Liverpool, and Sunderland; from scarlet fever in Sunderland; from whooping-cough in Plymouth; from "fever" in Wolverhampton, Bolton, and Sunderland; and from diarrhœa in Blackburn, Bolton and Gateshead. The 82 deaths from diphtheria included 46 in London, 9 in Leeds, 7 in West Ham, and 5 in Swansea. No fatal case of small-pox was registered last week in any of the thirty-three large towns, and no small-pox patients were under treatment in any of the Metropolitan Asylums Hospitals. The number of scarlet fever patients in these hospitals and in the London Fever Hospital on Saturday last, Oct. 29th, was 3024, against numbers increasing from 2178 to 2915 at the end of the nine preceding weeks; 335 new cases were admitted during the week, against 358, 357 and 381 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 263 in each of the two preceding weeks, were again 263 last week, and were 52 below the corrected average. The causes of 45, or 1·2 per cent., of the deaths in the thirty-three towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Bristol, Nottingham, Leeds, Newcastle-upon-Tyne, and in fourteen other smaller towns; the largest proportions of uncertified deaths were registered in Blackburn, Preston, Halifax, and Hull.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 20·7 and 19·0 per 1000 in the two preceding weeks, rose again to 20·0 during the week ending Oct. 29th, and exceeded by 2·1 per 1000 the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 15·7 in Leith and 18·5 in Edinburgh to 25·3 in Dundee, and 27·2 in Perth. The 603 deaths in these towns included 36 which were referred to diarrhœa, 15 to "fever" (principally enteric), 8 to diphtheria, 6 to whooping-cough, 4 to scarlet fever, and 4 to measles. In all, 73 deaths resulted from these principal zymotic diseases, against 105 and 86 in the two preceding weeks. These 73 deaths were equal to an annual rate of 2·4 per 1000, which was slightly above the mean rate last week from the same diseases in the thirty-three large English towns. The 36 fatal cases of diarrhœa showed a further decline from the numbers recorded in recent weeks, and included 9 in Glasgow and 8 in Dundee. The deaths referred to different forms of "fever," which had declined from 14 to 9 in the three preceding weeks, rose again to 15 last week, of which 10 occurred in Glasgow and 2 in Aberdeen. The fatal cases of diphtheria, which had been 8 and 6 in the two preceding weeks, rose again to 8 last week, of which 2 were registered in Glasgow, 2 in Dundee, and 2 in Aberdeen. The 6 deaths from whooping-cough showed a marked decline from recent weekly numbers, and included 2 in Glasgow and 2 in Aberdeen. The 4 fatal cases of scarlet fever were recorded in Glasgow, where 3 of the 4 deaths from measles were also registered. The deaths referred to diseases of the respiratory organs in these towns, which had been 141 and 120 in the two preceding weeks, were 119 last week, and were 18 below the number in the corresponding week of last year. The causes of 38, or more than 6 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had increased in the three preceding weeks from 22·1 to 26·0 per 1000, further rose to 26·4 during the week ending Oct. 29th. During the past four weeks the rate of mortality in the city has averaged 25·1 per 1000, the rate during the same period being 17·7 in London and 19·1 in Edinburgh. The 177 deaths registered in Dublin during the week under notice showed a slight increase upon the number in the preceding week, and included 13 which were referred to the principal zymotic diseases, against 18 and 20 in the two preceding weeks; of these, 4 resulted from diarrhœa, 4 from "fever," 3 from diphtheria, 1 from scarlet fever, 1 from whooping-cough, and not one either from small-pox or measles. These 13 deaths were equal to an annual rate of 1·9 per 1000, the zymotic death-rate during the same period being 1·7 in London and 1·1 in Edinburgh. The 4 fatal cases of diarrhœa showed a further decline from those recorded in recent weeks. The deaths referred to different forms of "fever," which had increased from 2 to 4 in the three preceding weeks, were again 4 last week. The 3 fatal

Digitized by Google

cases of diphtheria exceeded the number recorded in any week since May last, while the mortality from whooping-cough showed a marked decline. The 177 deaths in Dublin last week included 38 of infants under one year of age, and 49 of persons aged upwards of sixty years; the deaths of infants showed a further decline, while those of elderly persons exceeded the number recorded in any recent week. Ten inquest cases and 5 deaths from violence were registered; and 62, or more than a third, of the deaths occurred in public institutions. The causes of 13, or more than 7 per cent., of the deaths in the city last week were not certified.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

STAFF-SURGEON JOHN LEONARD AHERNE, has been allowed to withdraw from Her Majesty's Naval Service with a gratuity.

The following appointments are notified:—Staff Surgeons: J. Sugrue to the *Devastation*, and H. W. G. Doyne to the *Collingwood*. Surgeons: E. Cooper to the *Buzzard*; E. D. J. O'Malley to the *Jaseur*; J. Shand to the *Brisk*; D'Arcy Harvey to the *Excellent*; W. R. Trythall to the *Daphne*, undated; E. B. Pickthorn to the *Centurion*; and L. E. Dartnell to the *Tamar*.

ROYAL ARMY MEDICAL CORPS.

Lieutenant-Colonel Robert H. Robinson is placed on retired pay. Lieutenant-Colonels John Stevenson and Alexander S. W. Young retire on retired pay. Lieutenant O'Gorman is posted to the Dublin District for duty. Captain Way will be held in readiness for service in South Africa. Lieutenant-Colonel Hughes has arrived at Canterbury for duty. Major H. N. Thompson has arrived at the Station Hospital, Hounslow, for temporary duty.

INDIA AND THE INDIAN MEDICAL SERVICES.

The Queen has approved of the following promotions among the officers of the Indian Medical Service made by the Government of India:—To be Surgeon-Colonel: Brigade-Surgeon-Lieutenant-Colonel David Sinclair, Madras Establishment. Surgeon-Lieutenant-Colonels to be Brigade-Surgeon-Lieutenant-Colonels: *Madras Establishment:* Henry FitzLawrence Plunkett French Esmonde-White, William Richard Browne, Arthur Henry Leapingwell, Hazlett Allison, and Thomas James Hackett Wilkins. *Bombay Establishment:* John Philip Greany. Surgeon-Lieutenants to be Surgeon-Captains: *Bengal Establishment:* John Stephenson, Frank Needham Windsor, Walter Barrie Turnbull, Ernest Edwin Waters, Asher Leventon, and Philip Francis Chapman. *Madras Establishment:* Frederick Linton Blenkinsop, Edmund Moritz Illington, Thomas Edgar Watson, and Charles George Webster. *Bombay Establishment:* Alfred Hooton, Arthur Frederick William King, Robert Frazer Standage, Andrew Armstrong Gibbs, and Henry Alfred Forbes Knapton. The Queen has also approved of the retirement from the Service of the under-mentioned officers: Surgeon-General James Cleghorn, Bengal Establishment, and Lieutenant-Colonel James Joseph Moran, Madras Establishment. The Queen has also approved of the resignation of the Service by the under-mentioned officer: Captain William Carr Sprague, Bombay Establishment.—*London Gazette.*

ARMY MEDICAL RESERVE OF OFFICERS.

Surgeon-Captain H. G. Thompson, to be Surgeon-Major. Surgeon-Lieutenant Edmond U. F. MacW. Bourke, 18th Middlesex Volunteer Rifle Corps, to be Surgeon-Lieutenant.

VOLUNTEER CORPS.

Rifle: 18th Middlesex: Surgeon-Lieutenant C. Godson to be Surgeon-Captain.

THE TITLES OF RETIRED ARMY MEDICAL OFFICERS.

The Royal Warrant recently issued with reference to the Royal Army Medical Corps, while giving satisfaction to officers on the active list does not relieve retired but employed members of the Army Medical Service from designation by cumbrous and inconvenient titles such as Brigade-Surgeon-Lieutenant-Colonel. It should not be a difficult matter for the authorities to confer upon these officers the same titles as those now granted to the R.A.M.C., and Lord Lansdowne would earn the gratitude of the retired as he has done of the active medical members of the Army by such a concession.

ARMY MEDICAL SCHOOL, NETLEY.

The following is an additional list of surgeons on probation nominated for the R.A.M.C.: J. M. Sloan, Glasgow University; W. W. Scarlett, School of Surgery, Royal College of Surgeons, Ireland; D. S. Harvey, Glasgow University; G. C. Phipps, Owens College, Manchester; and F. J. Brankenridge, St. Thomas's Hospital.

OOTACAMUND.

This well-known hill station of Madras has of late had the reputation of being exceptionally unhealthy and the Madras Government directed their Sanitary Commissioner, Colonel Thomson, I.M.S., to proceed to Ootacamund to investigate and report thereon. This has accordingly been done.

Professor A. E. Wright, M.D. Dub., Professor of Pathology in the Army Medical School, Netley, has been selected to proceed to India at once as a member of the new Commission appointed to study the spread of the plague. During his absence Major D. Semple will act as Professor of Pathology in the Army Medical School. Major C. Birt, R.A.M.C., is to succeed Major Semple as Assistant Professor of Pathology, while Captain G. Lamb, of the Indian Medical Service, has been appointed for one year as an Extra Assistant in the Pathological Laboratory of the Army Medical School.

Correspondence.

"Audi alteram partem."

"THE LANCET ANALYTICAL COMMISSION ON SHERRY: ITS PRODUCTION, COMPOSITION, AND CHARACTER."

To the Editors of THE LANCET.

SIRS,—I have read your most interesting article on Sherry. A similar description and analysis of Australian brandy which you issued some years ago has been the means of furnishing the profession with a genuine and good article. The need of pure, unadulterated wines and spirits is greatly felt by all who have to prescribe for gouty, dyspeptic, and "livery" subjects. You would add very much to the value of your work on sherry if you would trace the wine from its importation at our docks to its arrival on our tables. Is it adulterated by the British wine-merchant? I have at times questioned several friends "in the trade" on this point. They all assured me that the "blending" of sherry is essential and universal. The blending consists of adding water, spirits, curaçoa, burnt sugar, &c., and variously mixing different casks of sherry, so they told me. The British public will not drink it in its pure state, but demand this adulteration and alteration. I have some natural sherry that I get at the stores, discovered after hunting for it for some time. Being a dyspeptic I can drink very little wine, but this agrees with me and I like it. It is a light wine, dry, free from burning taste, and fruity in flavour. But I find that the ordinary guest at my table does not like it—the man, that is, who rather fancies himself as a connoisseur in wines; so that my friends the wine-merchants, who told me the British public will not drink "natural sherry," I now find are about right. How many people one meets say they cannot drink sherry. It would be a great advantage if some sherry importers would guarantee to sell nothing but the pure wine as imported; we could then recommend it with confidence to those who are poisoned by the usual stuff.

I am, Sirs, yours faithfully,

H. HOWARD MURPHY, M.D. Cantab.

East Twickenham, Oct. 29th, 1898.

"MEMBRANOUS RHINITIS AND ITS RELATION TO DIPHTHERIA."

To the Editors of THE LANCET.

SIRS,—May I be allowed to correct the figures given in your report in THE LANCET of Oct. 29th of my remarks in the discussion following Dr. Lack's very interesting

Digitized by Google

paper on Membranous Rhinitis and its relation to Diphtheria, read at the Royal Medical and Chirurgical Society on Oct. 25th? Doubtless I failed to make them sufficiently clear, but as they may be published in another place, I would like to have an opportunity of preventing any apparent discrepancy between their final appearance and that which they present in your report. I examined 125 children. Of these 69 had nasal discharges of varying quality and 56 were free from discharge. Of the former 37, and of the latter 24, presented the Klebs-Löffler bacillus; 5 cases where the discharge was more or less blood-streaked gave the bacillus in every case. None of the discharges were associated with constitutional symptoms not otherwise to be accounted for; all were of a markedly chronic character, and several of the children on the surgical side were apparently in good health, being admitted for accident or deformities. Trusting you will find space for this statement, I am, Sirs, yours faithfully,

THOS. D. LISTER,
Pathologist, East London Hospital for Children.

Wimpole-street, W., Oct. 28th, 1898.

THE WATER-SUPPLY OF LEICESTER.

To the Editors of THE LANCET.

SIRS,—As one who is interested in water-supplies in general and the question of the causation of endemic goitre in particular allow me to say a few words on this matter. The question of the Leicester water-supply seems to me one for very serious consideration. The upper reaches of the Derwent derive their water, at any rate in part, from well-known goitre-stricken geological horizons, the lower carboniferous limestone and Yoredale series of the carboniferous formation. The most goitrigenous water in my experience is that which remains quietly in contact with the soil (in affected localities), such as is the case with well water. It is found that when water originally goitrigenous flows away from its source, especially if exposed to the oxidising agencies of oxygen or light, it quickly loses its poisonous properties. Now will this be the case with the water of the Upper Derwent Valley and will the conveyance by pipes render the water innocuous on its arrival at Leicester? Personally I think that even in this latter case the water will lose the greater part of its poisonous properties, though I doubt if all will be eradicated. Most certainly also should the water be subjected to thorough filtration, another agency found to be efficacious in diminishing the amount of the goitrous poison. Another element of danger, it seems to me, in this Leicester case is that natural reservoirs are to be formed, so far as I can ascertain, and these in a goitrous locality. As to the question of the causation of the malady I think it quite time that the ancient theories of lime and magnesia were relegated to some museum of antiquities. On two formations in this country, largely goitre-stricken, hardly any lime or magnesian salts exist—viz., the Ordovician shales and the Volcanic Series of Borrowdale. The cause of the malady is rather to be sought in the agency either of soil-bacteria (or possibly hæmatozoa having a soil origin), or, secondly, of metallic salts, especially the sulphides of iron or copper (or rather the results of their decomposition). With regard to soil-bacteria certain chemical factors in the soil favour their growth no doubt, and this may account for the presence of goitre in particular localities. With regard to the goitre-producing faculties of decomposing iron and copper pyrites the evidence in their favour is very convincing. For example, in the lower carboniferous limestone, and Yoredale series I have found abundance of iron pyrites occurring as marcasite. Ordovician shales contain a large amount of cubical iron pyrites and marcasite. The English chalk formation, according to Berry, has goitre fairly evenly distributed though not to any extent (if lime salts caused goitre we should expect a large amount of goitre on this formation). Now with the exception of disseminated lime phosphate and glauconite I am unaware of any mineral in this formation except marcasite, which I may mention is a very readily decomposed form of iron sulphide. The gault clays of England are goitrigenous and their blue colour is due to disseminated iron pyrites. On the corresponding formation in France (*marnes aptiennes*) Saint Lager found an abundance of goitre with a corresponding abundance of the mineral in question. Many other instances could be adduced in favour of this theory and adverse to the lime and magnesian salts theory, but I think I have said enough to draw attention to this fascinating subject, as I consider too little attention has been directed in this country to a disease which has such a baneful influence on the health and intelligence of the affected localities.

I am, Sirs, yours faithfully,

LOUIS E. STEVENSON.

Temple Sowerby, Penrith, Oct. 28th, 1898.

"WHAT IS 'FIRST AID'?"

To the Editors of THE LANCET.

SIRS,—Dr. Clayton Jones brings out in his letter some other points in the teaching of "first aid" which also require considerable reform and I am glad to find that he agrees with me in desiring a more definite course and a more practical scheme of instruction. He has "not much faith in representative committees and ..... would rather see an able man appointed who should write a new text-book." I am not fond of such committees either, but it is not of much use that "an able man" should write a new text-book without some previous assurance that it would be accepted as the recognised manual and that the present state of things would not continue. Again, who is to appoint him? Instruction in "first aid," although largely in the hands of the ambulance department of the Order of St. John of Jerusalem, is not entirely so, and what is wanted is complete and definite agreement among the various authorities as to the scope of the subject and the method of teaching. Provided, however, the end is attained I do not much care whether it is by committees or otherwise, but I feel sure that reform of the kind indicated by the correspondence in your columns would be welcomed by all really interested in the proper teaching of "first aid."

I am, Sirs, yours faithfully,

Suffolk-street, S.W., Oct. 29th, 1898. VALENTINE MATTHEWS.

THE PLAGUE IN INDIA.

To the Editors of THE LANCET.

SIRS,—Your otherwise fair leading article in THE LANCET of Oct. 22nd on "The Indian Government and the Plague" contains some sentences from which it would appear that the natives of India are hostile to the *legitimate* steps which have been taken to stamp out the plague. That is a chimera which is affectionately hugged by a large majority of the British public. You quote the words of the Indian Government, "To attempt by force to eradicate a disease when the entire population exerts itself to oppose the methods adopted is an effort doomed to failure." In what way does the "entire population exert itself to oppose the methods adopted"? It is not the necessary steps to which they object, for disinfection, though not always with the modern therapeutic agent, is practised night and morning in every Indian household. Isolation is an ancient custom among the small-pox ridden people of India and inoculation as a science was practised in the East from time immemorial and, indeed, spread from the East to the West. So that in principle there is nothing which is being done which can be called an innovation. What they really object to (and what self-respecting nation would not?) is the arbitrary and high-handed manner in which the orders of the Government are executed. I do not say that it was the intention of the Government that its officers should ride roughshod over the people, far from it. But it is a notorious fact that the feelings of the people were grievously trampled upon; it may be from ignorance of Indian customs and manners. The Government cannot be altogether guiltless when it rejected the counsels and coöperation of the natives of the country and imprisoned without trial (a privilege given the meanest of Her Majesty's subjects in England) two highly born leaders of the people for sounding the warning note against some of the unpopular plague measures which had to be cancelled afterwards, but not till a serious riot had opened the eyes of the Government. By appointing a committee of investigation at the tail end of the outbreak the Government earns for itself the compliment of "being better late than never." As regards M. Haffkine's system of inoculation it seem to me that there is much ado about next to nothing. Whatever may be

Digitized by Google

proved in the future as regards the value or efficacy of his system, certainly the medical profession "do not yet know enough," as you rightly say, "to decide positively whether it is efficacious and if so how long the immunity conferred by it lasts, or whether it is a practicable scheme to apply in India with its teeming millions."

The English people have misunderstood the attitude of the Indians towards measures which, after all, have not yet passed the experimental stage. Even in England, where popular education is supposed to have done wonders, we see the ridiculous sight of the repeal of the vaccination laws, which have been acknowledged by all, except a handful of fanatics, to have stemmed the tide of small-pox. If such a thing can happen here much that has actually, and said to have, occurred in India can be easily explained and pardoned.—I am, Sirs, yours faithfully,

SARAT K. MULLICK,

National Hospital for Heart and Paralysis, Soho-square, W. Oct. 29th, 1898.

"MEDICAL FEES FOR LIFE INSURANCE EXAMINATIONS."

To the Editors of THE LANCET.

SIRS,—With reference to the letter from Mr. Paulin in THE LANCET of Oct. 29th I am glad to note that the invaluable services rendered by medical men in life insurance cases are becoming well recognised. These services are indispensable. On the honour and skill of the medical examiner depend the benefits the public derive from life assurance. This office has for some considerable time paid two guineas for £2000 cases, but my appreciation of the assistance rendered by medical men is such that I am about to propose to my directors that in future we pay an extra guinea for each £1000 above that amount. Though in all cases the examination should be equally thorough, still the responsibility which doubtless the physician feels in examining for large amounts should, in my opinion, be recognised.—I am, Sirs, yours faithfully,

HENRY R. POPE, Secretary.

The Absolute Life Assurance Company, Limited, 87, St. James'-street, Pall Mall, S.W., Oct. 29th, 1898.

"VITALITY."

To the Editors of THE LANCET.

SIRS,—Dr. Beale seems in his last letter to be just a little impatient because your correspondents have in their discussions confined themselves chiefly to the philosophical aspect of the question of vitality. The importance of this phase of the subject to the general practitioner will be more easily realised by Dr. Beale when he considers how little time the busy practitioner can afford for the prosecution of microscopical research involving laborious minuteness and lengthy sittings and that he, not having the opportunity of attacking such problems experimentally with the resources of a laboratory, does what is next best—reflects and philosophises. The statement that the philosophical side of the subject has to be studied and discussed in order to provide a harmonious whole of that which in honour of its chief exponent one may term *Bealeology*, needs no elaboration of reasons; the city doctor and the country practitioner will the more readily accept Dr. Beale's conclusion—drawn from an immense amount of microscopical study—if reasonable theories can be formulated as to the origin, the means of existence, and the "death" of vitality.

The question of the origin of vitality interests me as it does Dr. Hooper; if vitality be not a form of matter or motion where did it spring from? How did it reach the earth? It is generally admitted that the earth, a combination of matter and motion, is derived from the sun. It must at first, then, have gone through a long period of cooling and life could only have begun to exist in the fashion we now see it when the earth reached a certain degree of temperature and presented other favourable manifestations of motion, such as a non-injurious state of electrical environment, suitable atmospheric conditions, and proper juxtaposition of the constituents of primeval bioplasm. Given the presence, then, of these conditions, from what sources did vitality arise and by what way did it arrive? The question of its source and means of reaching the constituents of bioplasm is intimately bound up with our conception of its mode of action on antebiotic material and its manner of becoming latent and conserved when bioplasm dies. (Whether one takes Dr. Beale's view of life or the mechanico-chemical theory one feels bound to accept indestructibility as an attribute of it.)

Is vital power derived from the sun just as motion is, and was it latent until conditions arose when it could blossom forth? Or is this subtle influence transmitted (possibly by vibrationary means) through the intra-astral medium from some extra-solar quickening centre? (How near does this bring us to the conception of a life-giving Almighty.) Vitality must have originated in either of these ways or else must be considered a manifestation of motion—having distinct and peculiar properties it is true—and classified amongst the forces of the natural sciences that are so interdependent on each other and without the aid of which vitality can show no results.

I am, Sirs, yours faithfully,

Cowling, Yorkshire, Nov. 1st, 1898. JOSEPH H. ROWE.

A RARE DISLOCATION.

To the Editors of THE LANCET.

SIRS,—On Oct. 28th I was called to see a woman who had been attended by a midwife in her confinement fourteen days previously, but a lump being observed in the infant's neck she had been advised to have a medical man to see it. I found the child small in size but in fair condition. It naturally turned on its left side, twisting its face downwards towards the left shoulder. Examination showed dislocation of the sternal end of the right clavicle, the bone being drawn upwards and slightly outwards by the sterno-mastoid as far as the subclavian, which retained the outer half in its place. This was a breech presentation, and the mother stated that the midwife had had great trouble with the after-coming head. I cannot find this cause mentioned in the text-books and thought it might interest some of your readers.

I remain, Sirs, yours faithfully,

Bournemouth, Oct. 31st, 1898. A. J. TURNER, M.D.

"DR SAUNDBY'S ADDRESS."

To the Editors of THE LANCET.

SIRS,—Dr. Saundby, in his address to the students at Cardiff, admits that our country is saturated with the commercial spirit and that students, professors, and governing bodies are all alike too apt to consider what will pay them best. Some time since your Commissioner had occasion in the interests of the profession to visit Birmingham, and in the first instalment of an excellent report published in THE LANCET he brought a charge of commercialism against the whole community. This did not please the President of the Council of the British Medical Association, and when your Commissioner afterwards called upon Dr. Saundby he was told curtly to mind his own business. What is the difference, we may ask, between the term "commercialism" as used by your Commissioner and the phrase "saturated with the commercial spirit" as employed by Dr. Saundby?

Dr. Saundby pleads for the establishment of eight additional universities in England alone. Those, we gather, would cost £16,000,000 and would require for their maintenance the sum of £400,000 per annum. Dr. Saundby speaks of millions sterling as glibly as any company promoter, but when the decaying medical school of Birmingham has been replaced by an up-to-date and model university is it probable that Dr. Saundby will trouble himself further with the £14,000,000 which would still be required to found similar and consequently rival universities in Manchester, Liverpool, Leeds, Newcastle, Bristol, Nottingham, Norwich, or that other city not specified? I hardly think so. Dr. Saundby at first allows that "there may be professions in which the work is better paid and less exacting," but later he expresses the somewhat contradictory opinion that "there is no profession in which success more certainly attends attention to business or in which so good an income can be as readily secured." If the latter statement be true I can only say that the condition of the other professions must be deplorable indeed. Mr. Lawson Tait has spoken regretfully of the mean dwellings now occupied by so many medical men of good character and recognised ability in the city of Birmingham, and judging from the rents paid, as indicated by Mr. Tait, such dwellings certainly could be fittingly

Digitized by Google

occupied only by humble individuals of the working class. From a leading article on the "Sixpenny Doctor" in the most widely read of Birmingham newspapers I cull the following: "The simple fact is, and there is no good purpose to be served by disguising it, that the medical profession in common with others is overcrowded. Of late years there has been an increase in the number of medical colleges and the cost of an ordinary medical education has been decreased. ..... How the medical bodies are to prevent the excessive rush into the profession we do not quite see unless they can persuade the universities and medical colleges to raise their standards and their fees and so diminish the number of entrants. When a man has once qualified he naturally and properly expects to live by his profession. He takes guineas if he can get them, if not he accepts half-crowns, and if even these become too scarce he swells the ranks of the sixpenny doctor." The following extract from a professional journal has been widely circulated in the public press: "Now we speak but plain and sober truth when we say that competition in medical practice at the present time is excessive and ruinous; and this is true of all ranks in the profession. ..... We feel and know that the vast majority of doctors in full practice have to reckon with a diminishing instead of an increasing income year by year; that old men are steadily elbowed out, and not having been able to save any money at all in early life they are often driven to starvation, whilst young men coming in and endeavouring to establish themselves quite justifiably in practice against their older rivals are often compelled to resort to methods which are nothing less than degrading. The following is a generalisation from twenty years' practice in London. Of every six men who take a house and put up a door-plate without buying a practice, five are compelled to leave the house within two years. They leave with their little capital expended and with despairing hearts to renew the struggle elsewhere."

Dr. Saundby says further: "Our position depends mainly on the public belief that we are a disinterested profession, and that belief rests upon the vast amount of public work we do for nothing." What is the nature of the work to which Dr. Saundby refers? We do work for nothing when, from disinterested motives, we give our services freely without thought of fee or reward, and we also do work for nothing when in the ordinary course we give our services in anticipation of payment which in the end is not forthcoming. Our good deeds and our bad debts represent a vast amount of work no doubt, but such work is not paraded in full view of an admiring public. It is true that the hospital physicians and surgeons of Birmingham alone do a vast amount of work without remuneration, but surely they have their reward. Is not the gratuitous advertisement inseparable from such appointments worth infinitely more to the man who knows how to make the most of his opportunities than the full value of the work which he does for nothing? If Dr. Saundby had said: "In Birmingham there is no profession in which success more certainly attends attention to business, or in which so good an income can be as readily secured provided you have a hospital appointment," one statement at least in the elaborate address would have been undeniably true.

I am, Sirs, yours faithfully,

J. RITCHIE DALRYMPLE.

Yetholm, N.B. Oct. 15th, 1898.

"THE PHYSIQUE OF BOYS ENTERING PUBLIC SCHOOLS."

To the Editors of THE LANCET.

SIRS,—It is incumbent on me, in consideration of your kindly and courteous notice of my letter to the *Times*, giving the result of the physical examination of 100 boys as they entered a public school, taken consecutively and unselected, to amplify my letter by furnishing you with the further particulars you indicate as of value. With reference to the deformities, it seems to me to be possible that the examiner might have been a little over severe had he been preparing the results of his examination for publication, but when this was a mere after thought and the examination was solely for the purpose of regulating the physical exercises and games of each boy it seems scarcely possible. I had known for many years that these deformities were considerable and that they were mainly the result of negligence in the process of education, but I was myself astounded at the facts revealed by the examination when I came to total them. The cardiac cases were mitral disease and the hernias were congenital.

You suggest that a medical account of the antecedents of the cases of albuminuria would throw a flood of light on the pathology of the so-called functional albuminuria. I am fortunately able to accede to your appeal, having by my side a complete previous medical history of every boy. I fear, however, it will not prove of value in its elucidation. I have little doubt in my own mind that this form of albuminuria in boys, like chilblains, is dependent upon the condition or action of the vaso-motor nervous system. Else how is it that in the worst cases where the urine boils as white as milk the albuminuria disappears as soon as the boy is placed in the horizontal position, in which position he can be fed as heartily as is pleased, and it never appears unless he is very constipated? While in the vertical position, if it is to be kept away he can partake of nothing but milk, which even "crammers" know who send candidates up for the medical examinations of the public services. How is it, further, that these albuminurics can join in all vigorous school games, apparently without harm, and yet faint soon after rising in the morning, especially if they are compelled to stand? When these boys thus faint, or even feel faint, the first thing I do is to examine the urine. I can now diagnose these cases of albuminuria from their appearance, from a finger on the pulse, or my hand on the heart.

The Previous Medical History of 22 Boys suffering from Albuminuria between the Ages of Thirteen and Fifteen Years.

Name of disease.	Number of cases.	Name of disease.	Number of cases.
Chicken-pox	19	Acute nephritis	1
Whooping-cough	19	Pleurisy	1
English measles	17	Pleuro-pneumonia	1
German measles	7	Bronchitis	1
Mumps	7	Rheumatism	1
Scarlet fever	4	Laryngitis	1
Influenza (?)	2	Burmah malaria	1
Diphtheria	2	Hay fever	1
Headaches	2	Catarrhal jaundice	1

I admit that the record of the height, weight, and chest-girth are only of personal value to the master, to whom they are handed for his guidance in the management of the boy and to whom they are of untold value, for, taken periodically, they indicate as nothing else can when wrong is being done to the child in the process of education.

As these public school boys are a "special class," well-bred, well-fed, and reared for the most part in the country, I thought it only fair to employ the averages of the special class tables of Dr. Charles Roberts, as if such a very specialised class is compared with the artisan class reared in towns there is a very marked difference. For instance, the following shows the average height and weight of the artisan class—town population:—Age, 14 years; average height without shoes, 57·76 in.; average weight, including 9 lb. of clothes, 84·61 lb. The following also shows the average height and weight of the most favoured classes of the English population—public school boys, naval and military cadets, &c.:—Age, 14 years; average height without shoes, 61·11 in.; average weight, including clothes of 9 lb., 99·2 lb.

It seems to me, therefore, that it would be very misleading to take an average of all classes in estimating the average height and weight of such a very favoured class as public school boys. I am aware that the record of the physical examination of only 100 boys is scientifically of not much value, though I thought they were of untold value to the public as eye-openers for the coming generation. I am now preparing tables for a much more minute record, and when I have the physical examination of 1000 scheduled I will publish it. If I do not live to tell the tale my successor will find it in such order that he will have no difficulty in doing it for me. For obvious reasons I still withhold my name and sign myself,

Your obedient servant,

Oct. 31st, 1898. M.D.

A NURSES' HOME is to be erected in connexion with the Brompton Hospital for Consumption and Diseases of the Chest, the estimated cost of which is over £30,000.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

Manufacturers and River Pollution.

THE decision given in the Queen's Bench Divisional Court on the 27th ult. by the Lord Chief Justice and Mr. Justice Wills, however correct in law, is of evil omen as regards the purification of rivers. Two cases had been decided by the county-court judge against the River Ribble Committee, which had prosecuted two defendants for alleged pollution of the River Darwen by running solid putrid matter into the stream. The defendants were millowners on the river and had impounded the water in reservoirs, allowing it after a time to flow out again into the river through sluices, one of them merely opening the sluices and allowing the water and deposited matter to flow out as it would, while the other employed men to rake up the bottom of his reservoirs so that mud and all should run into the river. This was not held to make any material difference in the cases. No solid matter was put in by the defendants, but higher up the stream are paper-makers, who use esparto grass largely and are really responsible for the solid matter flowing from the river into the defendants' reservoirs. After being impounded for a time the matter in the water becomes putrid and is then turned into the river, causing a great public nuisance. Lord Russell said one question was, Did the defendants put into, or allow to be put into, the River Darwen putrid solid matter? As the analysis showed that the effluent where it entered the river from the reservoir gave only 2·4 parts of solid matter the judges held that it could not be said that the water in the river was polluted by putrid solid matter. What there was was put in by the paper-makers higher up and it would be hard for the defendants to be punished for the acts of others. The judges decided that no offence had been committed by the defendants under Section 2 of the Rivers Pollution Act of 1876 and that the summons should be dismissed under Section 17, which allows of impounding of water. It is allowable, therefore, to impound water, knowing it to contain putrescible matter, to keep it till a fine putrescent odour is obtained, and then to turn it into a river where it is abominably offensive for the delectation of the unfortunates lower down. The mud at the bottom of the reservoirs, if shovelled by spadefuls into the river, would no doubt be considered a solid, but according to this decision it seems that all one has to do is to stir up the filth and diffuse it through the body of the water in the reservoirs and then run it off. Is there no way of dealing with the paper-makers? The waste matter of the esparto grass would be a useful manure and it ought not to be very difficult to recover it.

The Training of the Feeble-minded.

A meeting was held in Manchester on the 26th ult. to form a society for promoting the welfare of the feeble-minded. The Dean of Manchester presided and said he should have hesitated before taking part in any new movement in Manchester amongst so many philanthropic enterprises which were carried on in the city had it not been for the necessity of the case. From an inquiry made under the auspices of the school board—of which the Dean is chairman—it appears that of 39,600 board school children 525 seemed more or less incapable of holding their own in the ordinary classes. Dr. Ashby was requested to see these children and he found that there were 214 "dull and backward," 276 "mentally feeble," 4 "deaf-mutes," and 6 not sufficiently behindhand to need special attention. The school board are about to erect buildings both in the north and south of Manchester as special schools for these children, but, as the Dean said, "the children who might leave the schools of the board needed further guidance." He moved a resolution—"That it is desirable to form a North of England society for the promotion of the welfare of the feeble-minded." This was seconded by Miss Dendy, a former member of the school board, who may be said to have been the active spirit in this movement. She said they wanted £20,000, which Manchester could easily provide. "The price of a dinner party, of a ball dress, of a Saturday's football match, and the thing was done." By what process of mental arithmetic this estimate was arrived at is not known, but a very small amount of self-denial widely distributed would soon suffice. Dr. Ashby, in supporting the resolution, emphasised the fact that other means than those provided by the school boards and the guardians of the poor were needed for dealing with feeble-minded children. The Duchess of Sutherland, as President of the National Society for Promoting the Welfare of the Feeble-minded, spoke strongly in favour of the object of the meeting. Sir Wm. Houldsworth moved the appointment of a committee with the Dean of Manchester as president of the society. He said that apart from Christian duty an important argument in favour of the work it was proposed to do "was the national argument of preventing the propagation of the present state of things to future generations."

Typhoid Fever at Stockport.

Dr. Porter, medical officer of health for Stockport, reports the prevalence of typhoid fever. He states that of 20 cases under notice 15 are, in his opinion, the result of soil and air pollution and, as he has repeatedly pointed out, "so long as such conditions continue just so long will very hot summers be, with almost absolute certainty, followed by a corresponding severe incidence of typhoid fever."

Cotton Districts Convalescent Fund.

The meetings of the governors of the above fund always bring back the remembrance of the hard days of the cotton famine, and the residue of the fund subscribed for the relief of the operatives is still the means of giving invaluable help to many poor convalescents. At the meeting on Oct. 24th the report stated that during the nine months ending Sept. 30th, 1898, 2295 patients had been sent to the convalescent hospitals at Southport, Buxton, and Cheadle, at a cost of £3592.

Infectious Diseases Hospital for Oldham.

The new infectious diseases hospital for Oldham was opened on the 26th ult. by the Mayor of the borough, Alderman Waddington. The old temporary structures have been swept away and replaced by a permanent building, the whole establishment being surrounded by a wall about half a mile in length. The wards will accommodate nearly 100 patients and in times of epidemic the accommodation can easily be increased.

Nov. 1st.

SCOTLAND.

(FROM OUR OWN CORRESPONDENT.)

Aberdeen Hospital for Sick Children.

ON Oct. 28th, Princess Henry of Battenberg came from Balmoral to Aberdeen to open a two days' bazaar in the Music Hall Buildings in aid of the Royal Hospital for Sick Children. The route from the Joint Passenger Station to the hall was gaily decorated and the weather was fine. Previously to the opening ceremony several presentations, including the members of the hospital medical and surgical staff, were made to Her Royal Highness, who subsequently made a number of purchases, and before leaving the city was entertained to lunch in the Palace Hotel by the directors of the hospital. On Saturday the bazaar was reopened by Lord Provost Mearns. The proceeds of the two days' sale amounted to £1440.

University of St. Andrews.

On Oct. 29th the recently appointed medical professors were installed:—Professor Stalker to the chair of Medicine, Dundee College; Professor Macewen to the chair of Surgery, Professor Muir to that of Pathology, and Professor Kynoch to that of Midwifery. Principal Donaldson administered the oath. There was a large attendance of students and others in the Library Hall, St. Andrews University, where the ceremony took place. Professor Lawson (English Literature) was installed at the same time.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The Royal University of Ireland.

THE ceremony of conferring degrees took place at the Royal University of Ireland on Oct. 28th in the presence of a very large and distinguished audience. The

Digitized by Google

Marquis of Dufferin and Ava, Chancellor of the University, delivered an address, in which he alluded to the recent institution of diplomas in agriculture by the Senate and to the work which the University had done in certain spheres of physical research. The degree of D.Sc. (*honoris causâ*) was conferred on Sir Richard Thorne Thorne, K.C.B., M.B. Lond., F.R.S., and Professor Thomas Preston.

Treatment of Epileptics in Irish Workhouses.

The Countess of Meath has recently addressed a letter to the Dublin morning papers calling attention to the fact, elicited by her from the medical officers of several unions, that pauper epileptic patients are placed in the same wards as lunatics.

Mercer's Hospital, Dublin.

At a meeting of the Commissioners of the Pembroke township, held on Oct. 30th, a letter was read from the governors of Mercer's Hospital asking for a contribution in aid of the funds of that institution and stating that the Corporation of Dublin had withdrawn a grant of £300 which they had annually made. The secretary was directed to reply that the request could not be complied with.

Royal College of Surgeons in Ireland.

The ceremony of opening the School of Surgery took place on the afternoon of Nov. 1st, when the medals and prizes awarded during last session were distributed by Mr. Robert L. Swan, the President of the College.

North of Ireland Branch of the British Medical Association: President's Address.

On Oct. 27th, in the presence of a large audience of medical men, the incoming President, Dr. Henry O'Neill, inaugurated the present session by giving an opening address on Recent Advances in Brain Surgery. After thanking the members for the honour conferred on him Dr. O'Neill began by pointing out the special importance of head injuries and discussed the question of localisation of functional and motor areas in the brain. He thought that Professor Chiene's method for ascertaining the relations of the cerebral convolutions to the scalp the best and he hoped the members would soon have an opportunity of judging the undoubted value in surgical practice of a simple plan described by Professor Symington of Belfast at the late Edinburgh meeting for localising the motor areas of the brain. Dr. O'Neill dwelt very fully on the aseptic management and the technique of the surgical treatment of cerebral wounds in the operation of trephining and he gave an account of a series of cases to show the great success of cerebral surgery, the patients themselves being exhibited. Finally, he discussed the indications for operation in surgical injuries of the head. The address was illustrated by limelight views, which made it much more clear and striking, and Messrs. Down Brothers lent a series of recent types of instruments used in Brain Surgery. On the conclusion of the address a very hearty vote of thanks to Dr. O'Neill, moved by Professor Byers and seconded by Lieutenant-Colonel Moorhead, I.M.S., was passed. Communications on medical subjects were then brought forward by Mr. M'Harry, Dr. Dempsey, and Mr. Robert Campbell.

The Condition of Workers in Flax-scutching Mills.

A case of great importance to flax-scutching mill-owners was heard at Garvagh Petty Sessions (county Derry) on Oct. 27th, when the proprietor of a flax-scutching mill was summoned by the Commissioners, under the Factories and Workshops Act, to show cause why the order for the erection of a ventilating fan was not complied with. Her Majesty's Inspector under the Factories and Workshops Act brought the action in order to ameliorate the conditions of work in flax-scutching mills, the idea being that dust and other impurities were generated in, and inhaled by workmen in, this mill and that this could be prevented by the use of a fan or other mechanical means, which had not been provided although notice had been given, and that consequently the factory was not kept within the meaning of the Act. Evidence was given by the inspector, flax scutchers, Dr. Morrison (medical officer of the district), Dr. Steel (medical officer of health), and Dr. T. M. Legge (medical inspector of factories) to show that there was dust in the mill which was so fine that it would float in the air and would, after being inhaled, cause injury to the lungs. For the defence evidence was called to show that those examined had all had experience of working in scutch mills and that they had not suffered in health thereby. Mr. Cochrane testified that scutching would not affect a healthy person but would a person already diseased. The bench were about to impose a nominal penalty, but at the request of the solicitor of the mill-owner it was decided to impose sufficient penalty to allow the defendant to appeal, and this was accordingly done.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Peritoneal Immunity to Certain Operative Infections.

MM. AUCHÉ and CHEVANNAY of Bordeaux were able to communicate to the Society of Biology at its meeting on Oct. 25th some interesting results obtained by experiments in peritoneal infection. It is well known that in certain animals the peritoneum is able to resist the introduction of virulent cultures and MM. Auché and Chevannay have now been able to prove that the human peritoneum possesses the same power. They brought forward 5 cases in support of their argument: 2 were cases of total abdominal hysterectomy for fibroma; 1 an ovariotomy for cystic epithelioma of the ovary; 1 a laparotomy for tuberculous peritonitis, and 1 for contusion of the abdomen. All were operated on under the strictest antiseptic precautions and all made a good recovery. In 3 of the cases there was no peritoneal effusion; in the other 2—i.e., the contusion and the tuberculous peritonitis—there was effusion. From the first 3 towards the end of the operation a few drops of blood which had escaped into the peritoneal cavity were collected in Pasteur pipettes, while from the other 2 a little of the effusion was taken in the same way at the beginning of the operation. Lastly, as drainage tubes were employed in some of the cases fluid from these drains was collected at different periods. Cultivations were made upon bouillon and various solid media, with the result of convincing the experimenters that the peritoneum is always infected by an operation, as a rule by the staphylococcus albus, even if previous to the operation the peritoneal contents have been shown to be sterile. Fluid from the drainage-tubes taken three and five days after the operation showed both staphylococcus albus and aureus. MM. Auché and Chevannay conclude from these results that despite all the precautions taken by surgeons the peritoneum is more often infected during an operation than is commonly supposed, but that, as a rule, such infection does no harm. The influence of the personal resistance of the patient thus appears to be very considerable as was indeed always affirmed before the advent of micro-biology.

Splenectomy for Malarial Infection.

A paper on 22 cases of splenectomy for malarial infection was communicated to the Academy of Medicine on Oct. 25th by M. Jonnesco of Bucharest. The spleens removed weighed from 850 to 5750 grammes and in every case but one were firmly fixed by adhesions, while most of the patients were profoundly anæmic and cachectic. One patient only died from the operation and that death was from secondary hæmorrhage, while seven others finally succumbed owing to their generally unhealthy condition or to some complication independent of their malaria. In all there was rapid improvement in the proportion of red corpuscles and a diminution in the toxicity of the urine. These results M. Jonnesco considers enable him to confirm, as he had always been inclined to do, the theory of Laveran that so far from the spleen being a protective organ against malaria it is really a sort of reservoir for the hæmatozoa where they accumulate in the intervals of the paroxysms. To do away with the spleen is, therefore, to do away with the storehouse of infection.

Meeting of the French Medical Associations.

The annual meeting of the French medical associations (*syndicats*) was held on Oct. 25th at the Hôtel des Sociétés Savantes. Delegates attended from sixty associations. A number of subjects came up for discussion, of which the following were the most important. Protests were made against the new legal regulation concerning accidents to workmen whereby a wounded workman is considered as a pauper and the medical man is obliged to attend him at the tariff laid down by the Assistance Public for those patients who are charged nothing. Objections were put forward to the system of gratuitous medical assistance, and it was considered that distant visits in the country should be paid

Digitized by Google

for by mileage and that the choice of the medical man should be left entirely to the patient. A resolution was passed that promotion of medical men in the reserve and the militia and their right to reach the highest position should not be limited as at present to those on the staff of a hospital or the professors in a Faculty. A dinner was held in the evening with Professor Brouardel in the chair. In the course of his speech he remarked that he would do everything in his power to get the new regulation as to the 30-franc tax imposed by the Library of the Paris Faculty of Medicine rescinded.

A Patriotic Fête at the Charité Hospital.

The students working under Dr. Gouraud, who is physician at the Charité Hospital, and whose son Captain Henri Gouraud has just covered himself with glory in the Soudan by the capture of the well-known chief Samory, got up a *fête* in honour of the event. Dr. Gouraud's wards were ornamented with flags and flowers and many stirring speeches were made.

The Disinterestedness of Dr. Calmette.

Dr. Calmette, Pasteur's well-known pupil, who was recently appointed as chief organiser of the Pasteur Institute at Lille and who has won much fame by his researches into the question of immunity for serpent venom, has made another discovery of a more purely commercial nature. By this discovery he was enabled to manufacture alcohol very much purer and stronger than is usual at a distillery and at the same time much more cheaply. He sold his secret to a large factory near Lille and very soon realised the handsome sum of 250,000 francs. This sum he has handed over absolutely to the Pasteur Institute, over which he presides, although he is not personally a wealthy man. This act of munificence, which has been noticed solely by the medical press and ignored by the political journals, is considered as a protest against the recent action of Dr. Behring.

Obituary.

Dr. Pilliet, one of the best known histologists of the day, has just died after a long illness. He was curator of the Pathological Museum at the Faculty of Medicine (the Musée Dupuytren) and head of the laboratory of clinical surgery at the Charité Hospital.—Dr. Chipault, whose son is so well known for his researches on the nervous system and its bony coverings, died suddenly at Orleans while he was performing an operation.—M. Tocepart, a young house physician at the Tenon Hospital, died recently from typhoid fever contracted in the discharge of his duties. His death is all the more sad as his mother only the other day lost both her husband and her other son.

Nov. 1st.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

Professor Virchow.

THE winter session of the Berlin Medical Society began on Wednesday, Oct. 19th. The principal event of the first meeting was the enthusiastic reception given to the chairman, Professor Virchow, who had just arrived from England. The presidential chair was decorated with flowers, and when Professor Virchow entered the members rose to listen to an address of welcome read by the vice-president, Professor von Bergmann, who said that Professor Virchow had gone to England as a peaceful conqueror, that he had there worthily upheld the renown of German science, and that the society felt very proud of the high esteem in which their president was held by the most distinguished English *savants*. In his reply Professor Virchow said that he had been very much impressed by the cordial manner in which he was received by the members of the English medical profession. He had been anxious to satisfy such a critical audience as that connected with Charing Cross Hospital Medical School, from which men like Huxley and Livingstone had come. Referring to the present condition of medical science in Great Britain he said he was astonished at the development of experimental methods. When he was at the International Medical Congress held in London in 1880 medical science was severely threatened by the anti-vivisectionists, whom he, in company with his old friend, Sir James Paget, had to oppose. Now the anti-vivisectionists are obviously defeated and the victory of experimental medicine assured. Professor Virchow next touched on the recent opening of the new laboratories at Liverpool at which he was present, and pointing to the portraits of Lord Lister and Sir James Paget, which among other portraits of leading medical men adorn the assembly hall of Langenbeck House, he said that the services rendered to medical science by these two men were thoroughly well known to the meeting. On the conclusion of his speech, which was received with great applause, Professor Virchow took the chair, which had been occupied during the earlier part of the proceedings by Professor von Bergmann, and then the business of the society began. The meeting again stood up in token of respect to the memory of the members deceased during the recess—one of them being Professor Nasse, who had los his life by an accident on the Alps. The first paper, on the Etiology of Syphilis, was then read by a visitor, Dr. Nissen of Wiesbaden. The bacillus alleged by him to be the cause of the disease was not acknowledged either by pathologists such as Professor Wolff or by dermatologists such as Professor Lassar.

The Red Cross Exhibition.

An interesting exhibition lately took place in Berlin under the auspices of the German Red Cross Society. The principal aim of this society, as is generally known, is to support the official authorities in the care of sick and wounded soldiers in war-time, and in time of peace to provide aid for injured persons, the victims of epidemics, &c. The exhibition was divided, into eight sections: (1) first aid; (2) ambulances; (3) housing of sick and wounded soldiers; (4) domestic appliances for hospitals; (5) surgical appliances for hospitals; (6) nursing appliances; (7) clothing of ambulance men; and (8) literature. The Army Medical Department was very well represented in the exhibition. Arrangements had been made by this department to show in a very practical way to the public what is done with the soldier from the moment of his being wounded till his return home. This special exhibition took place on an extensive open space in connexion with the exhibition palace. The grounds were divided into different sections, each to represent a different phase in the treatment of the wounded soldier. The first section, marked "Truppen-Verbandplatz" (station for surgical dressings), showed the place where first aid is given by the surgeons accompanying the troops under fire; its equipment is, of course, very simple, consisting only of some litters, dressing boxes, &c. The second stage was represented by the "Haupt-Verbandplatz" (operation station), situated beyond the reach of the enemy's bullets. There the most urgent operations are to be performed and a much greater equipment is thus required. Ambulance waggons, vehicles with dressing material, surgical instruments, a pharmacy waggon, &c., were exhibited there. The third section showed the "Feldlazareth" (field hospital), of which every army corps has 12 of 200 beds each. A long column of carriages of every description exhibited the difficulty of carrying the equipment of such a hospital to the battlefield; there were carriages with tents, clothes for the wounded, bed-linen, surgical applicances, preserved provisions, &c.; a number of tents were also exhibited ready for use. From the field hospital the patients return home by the hospital train, expressly fitted for the transport of sick and wounded. A train consisting of hospital cars with beds, cooking cars, officers' car, pharmacy car, &c., was also on the grounds. During the journey the men get refreshments at the "Erfrischungs-Stationen" (refreshment places) provided and equipped by the Red Cross societies and at home they are at last received into the society's "Reserve-Lazarethe" (reserve hospitals), where they may stay till the cases terminate in recovery or death. The Army Medical Department's exhibition was made especially interesting by the fact that all the ambulance cars, hospital tents, and railway carriages were shown ready for use and fully equipped from the most complicated surgical instruments to the torches and electric apparatus which the ambulance men use in searching for the wounded after battle. The War Office has done well in proving to the public that nothing will be omitted to relieve the unfortunate victims of a possible war. The other sections of the Red Cross Exhibition showed hospital ambulances as used in the larger towns of Germany, and arrangements for first-aid in factories, in street accidents, &c. In connexion with the exhibition a congress of the Volunteer Ambulance Columns of Germany took place. The Berlin and Munich columns held a "manœuvre," its idea being that after a

Digitized by Google

battle near Berlin a great number of wounded still lie on the field and are to have their wounds dressed and to be removed by ambulances, trains, &c., to the hospitals. The surgeon-general, head of the Army Medical Department, Dr. von Coler, and many army and civilian surgeons were present at the "manœuvre," which proved a great success.

The Plague in Vienna.

The news of the outbreak of plague in Vienna has caused a great sensation here and there was some uneasiness felt lest the epidemic might spread to Germany by the manifold relations and the great traffic between the two countries. Now that the epidemic seems to be localised public opinion has become reassured; some journalists, however, seem to be afraid that a similar incident may occur also in this city. An interviewer calling at the Institution for Infectious Diseases was informed that cultures of plague bacilli in a virulent state were not kept there and that Professor Koch had strictly forbidden experiments with these dangerous bacilli. The *Official Gazette* also states that there are no virulent cultures of plague bacilli either in the above institution or in any other of the State laboratories.

Infra-clavicular Luxation of the Humerus.

In the *Berliner Klinische Wochenschrift* the late Professor Nasse described an interesting case of infra-clavicular luxation of the humerus observed by him in the Royal Surgical Clinic of Berlin. The patient was a man, fifty-six years of age, who had fallen from a horse and was admitted to the clinic ten days afterwards. There was great ecchymosis of the right shoulder and its surroundings, extending as far as the lower ribs and the elbow. Beyond the clavicle, notwithstanding the great swelling, a protuberance could be felt which proved to be the head of the humerus. The mobility of the joint was, of course, almost lost. The arm could not be brought to the side, elevation was impossible, and rotation and abduction could only be accomplished in a small degree. As attempts to perform reduction were unsuccessful owing to the humerus always gliding off the glenoid cavity, Professor Nasse decided on operative replacement of the humerus. Owing to the severe laceration of the muscles, which made efficacious aseptic treatment rather difficult, he resolved to wait for some days, but unfortunately the patient was attacked with delirium tremens and so the operation could not be performed before the lapse of three weeks. He made an incision beginning in the axilla and continued parallel to the inferior edge of the pectoral muscle, but when he attempted reposition in that way he met with an unexpected difficulty, for the hæmorrhagic infiltration of the muscles had in the course of time become transformed into hard, fibrous matter in which the head of the humerus was, as it were, immured, and it was impossible to draw it from the clavicle. The muscles were all torn off from their attachments and the glenoid cavity was covered with fibrous tissue. As there was therefore no prospect of a useful joint resection of the humerus was performed, with the result that the patient is now able to abduct the arm for about 45° and to raise it above the horizontal position. This case proves that operation should not be postponed but should be performed at once when reduction has proved unsuccessful. Infra-clavicular luxations are rather rare and only four cases have been examined anatomically. Reduction is always difficult and was especially so in the above case, where the capsule and the muscles had been completely pulled off. The difficulty of reduction was due to the circumstance that the capsule was either situated loose in the glenoid cavity or was kept strained by the muscles of rotation, the consequence being that the head of the humerus always slipped off the glenoid cavity.

Oct. 30th.

ERRATUM.—In the letter of our Berlin correspondent published on page 1092 of our issue of Oct. 22nd, the word "not" was accidentally omitted in line 10 of the first paragraph. The passage ought to read "should *not* be sent to Carlsbad first." The context shows with sufficient clearness that Professor Kehr disapproves of a routine system of sending every patient to Carlsbad and deferring operation till a case is desperate.

NEW SANATORIUM AT BRIGHTON.—The Mayor of Brighton, Sir John Blaker, opened the first portion of a new borough sanatorium on Thursday, Oct. 27th. The new buildings will cost about £19,775.

ROME.

(FROM OUR OWN CORRESPONDENT.)

"Down with Duelling."

"*Abbasso il duello*" rang from one end of Italy to the other when it became known that one of the most gifted and patriotic, if not the most wise, of Italians lost his life in a duel on March 6th last in the Roman Campagna. Felice Cavallotti, the "combatant Shelley" of his country's politics, had survived over thirty such encounters; Signor Macola, the antagonist who killed him, was a novice, not to say bungler, with the sword; and the unexpectedness of the result had, I suspect, not a little to do with the indignant outcry which followed it. Be that as it may, the trial of Signor Macola, which has just ended in his condemnation to thirteen months' imprisonment, seems to give general satisfaction, and will, it is hoped, be the prelude to a like intervention of the law on every repetition of the same offence. For duelling is by the criminal code of Italy a *delitto*, or crime, and its continuance is not only an outrage in itself but a direct encouragement to defy the law in every relation of life. With what consistency can the tribunals enforce their decrees when *avvocati* and members of Parliament, the makers and the upholders of law, are themselves the first to infringe it as often as a so-called "affair of honour" crops up? Poor Cavallotti will have done Italy a higher service than any he wrought her in his generously inspired but ecstatic and wayward career if by his tragic death he puts an end to duelling and makes the mediæval tradition which has disgraced the nineteenth century impossible in the twentieth.

Two Brigades of Artillery Poisoned.

At Brescia some thirty soldiers of the 16th Artillery having had their usual supper were immediately thereafter seized with violent abdominal pains accompanied by vomiting. Verdigris in the cooking utensils was at once suspected, but no trace of it was to be found and the food prepared and served in the same apparatus was next evening followed by the same symptoms. The food itself was next analysed, but no deleterious matter was detected in it. Poisoning, however, of a serious kind there has undoubtedly been, and, pending still more searching inquiry, the medical officers of the regiment suggest that the "pasta" or farinaceous element in the rations has been partially acidified, probably by the urine of rats in the store-rooms—a cause not unknown to barrack experience. Such "accidents" as the above are all too frequent in Italy. Mushroom poisoning is of more than weekly occurrence from the consumption of doubtful or deleterious fungi among the lowest classes, too poor to be fastidious or even careful. Ptomaine poisoning due to the ingestion of unsound fish destroyed nearly a whole family in Florence not so long ago, and infective pneumonia communicated from parrots became well-nigh epidemic in Genoa till the Uffizio di Sanità stamped it out by a veto on the harbouring of such household pets. Not till men and women in Italy are taught to be "the intelligent custodians of their own health" will such "accidents" become as rare as in the British Isles.

The English-speaking Practitioner in Italy.

The Congresso degli Ordini dei Medici, convened annually for the consideration and discussion of professional interests, deserves nothing but praise from the impartial outsider until it meddles with the practitioners of non-Italian nationality, whose *clientèle* is restricted to their compatriots resident in the kingdom. On Monday, Oct. 24th, the congress (the second of the series) met in the Aula Magna of the University and after preliminary business, including a report on the proceedings of its predecessor, it was addressed by Dr. Santini (a member of Parliament) on the subject he has made peculiarly his own—to wit, the right of medical men not furnished with an Italian diploma to practise in Italy. It had been thought that this *vexata quæstio* had been fairly and finally laid to rest last spring, when, intervening on behalf of Great Britain, Lord Salisbury induced the Di Rudinì Administration to let the duly qualified English-speaking practitioner pursue his calling as heretofore among his compatriots, that privilege being withheld from those only whose want of a diploma would have excluded them from the profession in their own country. This quite equitable arrangement, however, is far from satisfying Dr. Santini and the party—narrow, I believe, in numbers as in mind—for whom he speaks. At the

Digitized by Google

meeting above referred to he reopened the whole question, censured the Di Rudinì Government for having failed to give due consideration to a subject so important, and proposed the nomination of a commission empowered to wait upon the Ministers of the Interior, of Foreign Affairs, and of Public Instruction in the Pelloux Administration and to lay before their Excellencies the propriety of taking steps "affinchè ai medici Italiani sia concesso il trattamento che l'Italia faccia agli stranieri, e che sia radicalmente mutato o soppresso l'articolo 23 della legge sanitaria" (that Italian medical men be vouchsafed the treatment Italy metes out to foreigners and that Article 23 of the public health law be radically changed or suppressed). This proposal was carried in a "congress" of fewer than sixty members and a commission *ad hoc* was forthwith nominated, consisting of the Senators Durante (absent from "sciagura domestica" or family affliction) and Morisandi and the members of Parliament Dr. Santini and Dr. Angiolini (the latter representing the medical "ordine" in Florence). We are face to face, then, with a renewal of an agitation which was supposed to have happily died down, and we may expect to find the Pelloux Administration importuned with the pertinacity and energy brought to bear on its predecessor for the purpose of committing it to a policy which must end in excluding the English-speaking physician or surgeon unprovided with an Italian qualification from practising among his compatriots in the kingdom. This, and nothing less than this, is the end and aim of Dr. Santini's adroitly-drawn proposal, for ignoring the fact that Italians in the British Isles are numbered by units and the English-speaking world, migratory or resident, in Italy by tens of thousands, he requires a law to be exacted from the General Medical Council of Great Britain which would treat the Italian practitioner in England and the English practitioner in Italy as proportionally on the same footing, this preposterous demand being merely a cover for the real object of his agitation—to abrogate, that is to say, Article 23 of the Italian "legge sanitaria" which allows English-speaking medical men to cultivate a *clientèle* among their compatriots residing in Italy, while refraining from practice among the Italian population. It would be idle to reiterate the arguments already familiar to readers of THE LANCET by which the Di Rudinì Administration felt constrained to accede to the equitable requirements of Lord Salisbury and recognise the legal status of the English-speaking practitioner in Italy. I venture to predict that the renewed agitation will fare as badly as its defunct predecessor; and this for many reasons—one of which I may adduce. The sole supreme interest in the kingdom of Italy—an interest likely to be perennial—is the financial one. Year by year her ablest and astutest financiers are finding it more and more difficult to make ends meet. One-third of her revenue is derived from the annual sojourn within her borders of the English-speaking world alone, and that sojourn and the money it pours into her shrivelled circulation would be reduced by at least one-half if the medical attendance to which the said world is accustomed, in which alone it has confidence, and on which it counts, were denied it. She must, in other words, do everything to attract—nothing to repel—the wave of English-speaking travel which is annually to her what the yearly rise of the Nile is to Egypt; and if Dr. Santini and his following ever get so far as to "take the sense" of the Italian people and the Italian Parliament on their proposal they may expect to encounter as severe a rebuff as ever came from an indignant householder fighting *pro domo suâ*.

EGYPT.

(FROM OUR OWN CORRESPONDENT.)

Citadel Hospital.

MANY medical visitors to Cairo have seen and admired the English military hospital inside the lofty Citadel, with its walls and ceilings decorated in the Turkish palatial style, and the unique view of the neighbouring country obtained from its windows and balconies. Tradition says that the great Saladin chose this rock as the place to build his citadel, because he found that meat remained fresh there for a longer time than in other precincts of Cairo. But fresh air alone is, unfortunately, not enough to cure disease, and a week ago, when I was kindly allowed to visit the wards, I found them fuller than I had ever seen them before. In spite of the spaciousness of the building many convalescents had to find accommodation in tents in the garden. Altogether there were 458 sick and wounded British officers and men. This number included very little venereal disease—for that at least cannot be caught in the desert, but there were 120 cases of enteric fever and a large number of sufferers from dysentery. There were 50 wounded men all neatly bandaged with cyanide gauze and sal-alembroth wool. Since then 280 sick and wounded have been sent home to Netley in the transport *Jallunga*, and to-day the total number in hospital is 320. The temporary overcrowding has resulted from the rapid evacuation after the fight of all sick from the Nile stations to Cairo. This was considered advisable in order to secure for the sufferers a cooler climate and various luxuries as soon as possible. It was always foreseen that there would be a considerable number of sick after the campaign, and all difficulty would have been prevented if the home authorities had consented to supply a hospital ship. This ship, properly fitted up for the reception of sick and wounded, would have waited patiently in Alexandria harbour at the beginning of September. The sick, instead of being landed in Cairo, jolted 3 miles up the hill, and then allowed to suffer the damp heat of the worst month in the year in Cairo, would have continued their journey peacefully to the sea, where they would have been refreshed by cool breezes and the thought that they were really homeward bound. The ship when it had received its complement of sick would have proceeded immediately to England and would have saved much discomfort and perhaps some lives. But the penurious authorities in London decreed otherwise and poor Tommy Atkins has been going every day lately to the English cemetery in fours, fives, and sixes. There are now 80 cases of enteric fever in hospital and about the same number of dysentery patients. Until lately the percentage of deaths among the enteric fever cases was 11, but now it is a little higher. The dysentery cases have not been very severe and have yielded usually to the routine ipecacuanha treatment. The wounded have almost all done well, especially some sabre cuts. One man who was shot through the lung developed empyema. Perhaps the bullet took in with it some septic germs from the man's clothing. The hospital operating theatre has been greatly improved this summer and is now well furnished with modern aseptic instruments and materials. Adjoining it is a Roentgen ray department worked by the Royal Army Medical Corps, who tell me that it has been of great use to them. The hospital still suffers from the plague of bugs, which probably live in the wooden ceiling and lath-and-plaster walls. Colonel Barrow, the present senior medical officer of the hospital, has been waging war against them during the whole summer.

Enteric Fever and Dysentery.

All the cases both of enteric fever and dysentery are the direct result of the campaign. Some men sickened at the front, many on their way down the Nile, and dozens of others after their arrival in Cairo. The same course of events succeeded the Dongola and other sections of the Nile campaign. This time the Atbara station seems to have been specially productive of both diseases. Among other officers now in hospital there are two surgeons, one with dysentery and the other with enteric fever. How do the men get these diseases? Surely the troops infect themselves. One man develops enteric fever, pollutes the water long before his disease is recognised, and other cases follow. The camping ground left by one regiment is occupied by another which inherits germs and their vested interests. It is difficult to see how this will ever be prevented in time of war unless general officers will consent to a large supply of proper filters accompanying the army. This time the Berkefeld filters in the gun case invented by the Royal Engineers did very well, but there were not nearly enough of them. Men dying from thirst cannot afford to wait while water is boiled and cooled or even filtered for them. Another weak point of the filters is that means have not yet been provided for sterilising the candles of the filters. Instructions were issued to scrub the candles once a fortnight and then pass through them a solution of caustic potash. But if a filter is working for several hours in muddy Nile water it will require cleansing every day, and it cannot be trusted unless it has recently been sterilised as well.

Movements of the Royal Army Medical Corps.

Surgeon-General Taylor is proceeding to India, after a banquet which is to be given to him by the medical officers

Digitized by Google

to-morrow. Colonel Macnamara on promotion has left to take up the post of Principal Medical Officer at Gibraltar. Crete has absorbed 10 medical officers and a stationary hospital for 100 beds, besides large consignments of supernumerary stores. Twelve officers have been sent home to England and so there is a general dispersal of the large medical force, which all ranks praise in the highest terms for the excellence of the work done during great difficulties in the campaign. 21 officers were ordered to India, but no less than 11 of them were prevented by illness and had to be "invalided" instead. This week 8 officers are proceeding to India, and as some of them were warned that after the campaign they would have to continue their foreign service in India they made arrangements for doing so. But there are a few others now under orders for India who received no such intimation and on them the order falls particularly hard. A man is suddenly ordered on foreign service and at the end of hard work in an unhealthy climate he is told that instead of returning to his home and family he is to proceed to India for several years. This is quite unfair and has given rise to some not unnatural discontent here. The order has been made unnecessarily irksome by refusing leave to some officers who have been kept hanging about here with health impaired by their hard work and with nothing to do from the end of September to Nov. 2nd when they sail for India. These six weeks might have been more agreeably and profitably spent if leave to visit England had not been refused.

NEW YORK.

(FROM OUR OWN CORRESPONDENT.)

The Common House-fly the Carrier of Typhoid Germs in Camp.

THERE has been much speculation as to the great prevalence of typhoid fever in camps during the late war. Blame has been cast upon the water-supply of the camps, on the food, and on the surgeons. But it has been discovered at last that the common, busy house-fly has caused the typhoid fever in camps and is responsible for the deaths of hundreds of brave soldiers. This is the scientific conclusion of a commission of scientific men, appointed to investigate the condition of the camps, the cause of typhoid fever in them, and authorised to recommend measures to stop its spread and for its prevention in the future. The commission is a unit in declaring that the house-fly is responsible for the prevalence of typhoid fever in camps and brings forth apparently indisputable facts to support its conclusions. The report is of the greatest importance, not only to the War Department and the army, but to science itself, and will undoubtedly be the subject of much discussion. It will have great influence in determining the course of the War Department in the future in dealing with typhoid fever in camps and the members of the commission are willing to base their reputations as physicians and scientists on the accuracy of their conclusions. The commission visited the camps at Jacksonville, Huntsville, Fernandina, and Chickamauga. Everywhere it found typhoid fever and found it spreading. It found that in the majority of cases the typhoid fever was brought originally to the camp by regiments coming from the State camps. At Chickamauga the commission found the situation almost ideal; the ground was firm, the drainage was good, and the weather, though warm, was superb. Yet typhoid fever was prevalent there. The first question was, how did the fever get there? After investigation the commission concluded that it had undoubtedly been brought there from the State camps. The commission then sought to learn why the disease had spread and how it had spread. The water-supply of the camp was obtained from Chickamauga Creek and the water was said to be responsible for the spread of the disease. But one company did not get its water-supply from Chickamauga Creek, never did get its supply from that source, and yet many of its members were ill with the fever. The commission found that flies, as was naturally the case, were present in the camp by millions. It was the same way in every camp, their numbers being equalled only by those of the flies which infested Egypt during Pharaoh's plagues. The surgeons looked into the matter further and found that the flies fed from the fæcal matter from the hospitals and then at meal time shared the hard tack and bacon of the soldiers. In the first place the fly picked up on his six hairy little feet infinitesmal particles containing the germs of typhoid fever and in passing over the hard tack and bacon he deposited them there. One fly could do little harm, but millions of them conveyed a sufficient quantity of germs to inoculate large numbers of soldiers, which inoculation was slow but sure. The accuracy of this conclusion is, to the minds of the commission, amply demonstrated in the case of the company above mentioned, which drank no water from Chickamauga Creek. This company escaped the attack of typhoid fever until after a heavy and prolonged rainfall. Then a number of the members of this company were taken ill with typhoid fever, and the conclusion was immediately reached that its water-supply had become contaminated and that it was due to this fact that the fever made its appearance. But the medical commission holds that this was not the case, but that during rains and threatening weather flies seek for cover and become more persistent in their attentions to human beings than when they are able to skirmish for food in the open air. As soon as the rains began at Chickamauga the flies took refuge in the tents of this company and before they had been there long a number of the men were down with typhoid fever. It was found that in all the camps typhoid fever did not appear in isolated cases but that whole messes and in some cases whole tents of soldiers fell ill with the disease at the same time, showing conclusively that the fault lay with the food. At Jacksonville it was determined that fever was due to the fact that the sinks were connected with the sewers and frequently flushed. At Fernandina, where the system of tub-sinks was employed, it was found that this method worked very badly instead of very well, as was generally supposed. These tubs were collected every morning and hauled to a sewer and dumped; it was not possible to fill these tubs with dirt because they were dumped in the sewer, nor was any disinfectant used. These tubs were hauled through one street of a Wisconsin regiment and the fly was here busily at work. From the street he flew to the mess tables of the men in the tents, and as a result 50 per cent. of the men on the north side of the street were taken ill with typhoid fever, while the percentage of men ill from the same disease on the other side of the street was little lower. According to the commission the activity of the fly was not confined to the mess tent but he invaded the sleeping quarters of the men and exuded tiny bits of fæcal matter on their clothes and bedding, on their tent-flaps, and, in fact, everywhere, so that the very air itself was filled with fever germs. To prevent the ravages of the disease in the future the commission recommends that a new sink be used in the camps. It is now possible to have water connexions in every camp even where connexions cannot be made with sewers. It urged that metallic-lined sinks be constructed, 16 ft. in length, 2 ft. in width, and 18 in. deep, which troughs are to be slightly inclined and a connexion made with a water-pipe at one end. The other end is to project from the house and is to have a waste-pipe 3 in. in diameter and an upright pipe of the same diameter about 16 in. high. Every day this trough is to be filled with water in which a sufficient quantity of lime is to be placed. The waste matter will be thus disinfected as soon as it is deposited and all danger avoided. Every morning the sink will be cleansed by flushing it through the waste-pipe into a covered sink or into barrels properly covered and carried to some distant place for dumping. The commission also recommends that sinks shall be constructed in the future after the above pattern and placed on waggons, the whole apparatus being moved each day and the contents of the trough deposited in a safe place; such waggons could accompany the army on its march. It strongly urges that in every case great care shall be taken that such matter be disinfected as soon as possible by the use of lime or other disinfectants. The hope is that by this means the fly will be prevented from reaching the fæcal matter, or if he does it will have been disinfected and rendered harmless.

Yellow Fever in the United States.

Yellow fever which began to prevail in one of the ports on the Gulf of Mexico early in July, has continued to spread in spite of the most strenuous efforts on the part of the health authorities to control it. It is now prevalent in no less than twenty-six different towns in the States of Louisiana and Mississippi. Upwards of 800 cases have been reported with 50 deaths. The sanitary regulations to prevent its spread consist of an inspection of all railroad trains and disinfection of all cars, stations, and accessory buildings in the infected

Digitized by Google

district; but it is now evident that only severe frost will control its further spread.

Mortality among the Spanish Soldiers returning to Spain.

The reports from the transports which returned the Spanish soldiers to their native country show that the sickness and death-rate among these men had been very great. On one transport which carried 1000 Spanish soldiers 123 died on the voyage. This high sickness and mortality rate seems to have been due to the feeble condition of the Spanish soldiers resulting from the effects of the climate and improper and inadequate food.

Oct. 18th.

Obituary.

THOMAS HENRY MOXON, M.R.C.S. ENG., L.S.A.

MR. THOMAS HENRY MOXON was at the time of his sudden death on Sunday, Oct. 9th, the senior practitioner in Great Yarmouth. He was born at Hull in 1831, and in that town he commenced his medical studies at the now extinct Hull and Yorkshire School of Medicine. He was apprenticed to his brother, Mr. James Burdett Moxon, who then practised as a surgeon at Brigg in Lincolnshire, and who survives him. In 1853 Mr. Moxon took the diplomas of M.R.C.S. Eng. and L.S.A. He first commenced practice at Kirton-in-Lindsey, Lincolnshire, but after a few years he disposed of his practice there and went to Great Yarmouth in 1865–66, where he entered into partnership with his brother-in-law, the late Mr. Charles Palmer, and on the death of that gentleman in 1884 he succeeded to the entire practice. Throughout the whole of his professional life in Great Yarmouth he was looked upon by his brother practitioners as the soul of honour. He devoted himself with an untiring zeal and energy to his profession and was the possessor of a genial, kindly, sympathetic manner which made all classes of his patients look upon him as a true friend as well as medical adviser. The honour and dignity of the profession were ever matters of the highest concern to him both in his relations to the public and to his medical brethren.

For several years he served as a member of the Great Yarmouth School Board, working in the interests of the Church, of which he was a staunch and true member. Belonging to the older school of High Churchmen, he was tolerant of the views of others in Church matters to an unusual extent in one whose own views were so decided. He always took an active part in Church affairs and for many years was churchwarden to St. Andrew's Church. He was connected with the Volunteers for a long period, being allowed to retire last year with the rank of Surgeon-Lieutenant-Colonel to the 1st Norfolk Artillery Volunteers, E.D.R.A.; he obtained in 1897 the long service medal for thirty years' service and only this summer was presented by his brother officers in the brigade with a handsome testimonial. He was a member of the British Medical Association. In 1896 the medical men of Great Yarmouth united to form a district branch of the Incorporated Medical Practitioners' Association and Mr. Moxon was unanimously elected president. He filled the office for two years, but voluntarily retired at the commencement of the third year, the members of the branch presenting him with a piece of plate at their annual dinner in May last to mark their appreciation of his services as chairman as well as their personal esteem. Mr. Moxon was also a member and regular attendant at the meetings of the Great Yarmouth Clinical Society.

He was buried in the Great Yarmouth Cemetery on Oct. 21st. The funeral was attended by nearly every medical man in the town and a detachment of officers and men of the 1st Norfolk Royal Artillery Volunteers marched behind the hearse. A large number of the shops in the town were shaded out of respect to his memory and the church and graveyard were thronged by his fellow townspeople of all classes. He leaves behind him two sons and six daughters who deeply mourn the loss of as good a man and as good a father as ever lived.

CHARLES VAUGHAN SYMMONDS BENNETT, M.R.C.S. ENG., L.S.A., J.P.

THE death took place on Oct. 22nd of Mr. Charles Vaughan Symmonds Bennett, at his residence, Kensington House, Haverfordwest. Mr. Bennett received his medical education at Guy's Hospital, London, and took the qualification of M.R.C.S. Eng. and L.S.A. Lond. in 1858. The deceased, who was sixty-two years of age at the time of his death, had been in practice for many years in Haverfordwest and was formerly in partnership with the late Dr. Brown of that town. He was also surgeon to the Haverfordwest Infirmary and was a Justice of the Peace for Pembrokeshire and Haverfordwest. Mr. Bennett was highly respected and much regret is felt at his death.

MABEL ELIZABETH WEBB, M.B. LOND.

THE following notice has been sent to us by a member of the medical staff of the Royal Free Hospital:—"A few days since we were all saddened by the news of the sudden death of Mabel Webb at her mother's house in Hampstead. On the day preceding her death she was, as usual, at her work in the hospital and in twenty-four hours she was at rest from her earthly labours. For as long as fourteen years she had suffered from gastric pain, for which she was treated by several of the leading London physicians. Last Christmas, after a long period of latency, symptoms of fresh activity appeared and her medical attendant insisted on her relinquishing her work for a period of several months, which were spent in holiday on the Nile. From Egypt she returned in the early summer, seemingly in the best of health and free from all symptoms of the local trouble, and in thoughtfulness for the work of the hospital resumed her duties. On the evening of Oct. 27th she was seized with abdominal pain, but having experienced similar attacks previously she felt no alarm and thought it unnecessary to send for her regular medical attendant, who knew intimately the whole course of her illness. Next day, when surgical assistance was hastily summoned, all hope of life was gone and death from perforation of a chronic ulcer of the stomach followed in the course of an hour. By her untimely death at the early age of thirty-one years the Royal Free Hospital has lost a most valued servant. Graduating at London University in 1896 Mabel Webb was appointed Curator of the Museum at the Royal Free Hospital in the spring of 1897. Those of us who worked beside her well knew how faithfully she fulfilled her trust, out of sight of professional advancement, without a thought of professional reward. To many of us her life was at once a pattern and a precept, and those of us who had the privilege of her closer friendship feel that we have lost a sister. Bringing into her everyday work all the refinement of her personality she could not fail to exalt her office therewith. Such of us as were dependent on her assistance will sadly miss her ever ready service and unfailing courtesy; nothing was too trivial for her earnest attention. On the students of the hospital her loss will fall with special heaviness; it will indeed be hard to find another hand so ready to serve, so eager to help. By her death we are all the poorer."

Medical News.

UNIVERSITY OF EDINBURGH.—At the special graduation ceremonial held on Oct. 29th the following degrees were conferred:—

Degrees of Bachelor of Medicine and Master in Surgery.—Frederick Thomas Hield Adamson, Scotland; Arthur Leonard Anderson, New Zealand; Edmund Balmer Anderton, England; Frank Beecroft, England; Arnold Louis Joseph Branday, Jamaica; Harry Marchant Bundey, Australia; Duncan Alexander Cameron, England; Richard Craven, England; John Glen Forsyth, Scotland; Joseph Vincent Fox, England; Arthur George Hayden, England; Edith Isabella Hudson, India; Frederick John Jude, Australia; David James Cooper Oliver, Scotland; Duncan James Peirson, England; Dorothy Ellen Pratt, India; Thomas Pretsell, Scotland; Frederick William Price, England; Frederick Stanley Rose, Scotland; Alexander Hamilton Rutherford, Australia; Charles Robert Scott, Scotland; George Harper Wilson, Scotland; and John Brunyee Wilson, England.

Degrees of Bachelor of Medicine and Bachelor of Surgery.—Daniel Vere Maxwell Adams, Scotland; Anthon Sutherland Allum, Trinidad; Ernest George Ffrench, Jamaica; Edgar Robert Grey, B.A., South Africa; Albert Alexander Gunn, Scotland; Alexander George Hamilton, England; James Haworth, England; Joseph Hunter, Scotland; Balfour Stuart Hyslop, Scotland; Gerrit Hendrik Willem de Labat, South Africa; William Lockerbie, Scotland; David Valentine M'Intyre, M.A., Scotland; Andrew M'Kaig, Ireland; William Walker Maxwell, England; Philip

Digitized by Google

Ernest Millard, England; William John Nutter, England; Henry Kenneth Paxton, India; Ernest Cromwell Peake, England; Arthur de St. Leu Frederick Perigal, England; George Herbert Stewart, India; Arthur Henry Thompson, England; Peter George Leeb du Toit, South Africa; and Arthur George Worrall, Scotland.

Degree of Bachelor of Science.—Alan Wilfrid Cranbrook Menzies, M.A.

CARDIFF NATURALISTS' SOCIETY.—At the annual meeting of this society Dr. C. T. Vachell was elected President.

BATH RURAL DISTRICT COUNCIL.—At the meeting of the Bath Rural District Council held on Oct. 22nd it was decided to adopt the Infectious Diseases Notification Act.

MEDICAL MAGISTRATE.—Mr. E. Barnard Fuller, M.B., C.M., F.R.C.S. Edin., has been appointed a Justice of the Peace for the district of the Cape, Cape Colony, South Africa.

INCREASE OF A CORONER'S SALARY.—At a meeting of the Carmarthenshire County Council held on Oct. 26th the clerk read the warrant of the Home Secretary increasing the salary of the coroner for the Three Commotts and Kidwelly districts from £100 to £160 per annum. This was in direct opposition to the decision of the council.

ROYAL LONDON OPHTHALMIC HOSPITAL.—A ball will be held in aid of the funds of this charity at the Empress Rooms, Royal Palace Hotel, Kensington, on Friday, Dec. 9th. Vouchers for tickets will be obtainable only from the committee, medical staff, and ladies' committee, and all communications on the subject should be addressed to the secretary, Royal London Ophthalmic Hospital, Moorfields, E.C.

VACCINATION OFFICERS AND THE NEW ACT.—On Saturday a special meeting of the members of the Vaccination Officers' Association was held at the offices, 4, Bessborough-street, St. George's, Hanover-square, W., for the purpose of considering: 1. The report of the deputation recently appointed by the Association to wait upon the Local Government Board with respect to the new Vaccination Act, 1898, so far as it affects vaccination officers, and (2) to confer as to the new orders thereon which have been issued by the Board. Mr. E. A. Frith (Marylebone) presided in the unavoidable absence of the President, Mr. Shaddock, and there was a large attendance of members.—Mr. C. O. Elkerton, the hon. secretary, reported that the committee—Messrs. Shaddock, Walter, and himself—had made every effort to obtain an interview with the Local Government Board, but without success. This appeared to be inexplicable, as the Board had received a deputation from the public vaccinators, notwithstanding that the request of the Association to be heard had been sent in some considerable time before them. The committee, however, had drawn up a complete statement explaining the views of vaccination officers with regard to the Bill and that statement had been duly submitted to the Local Government Board. He was glad to say that whether consequential or not the age limit had been reduced from twelve to six months, and provisions inserted to pay vaccination officers per head on the birth-rate, in addition to payment on successful vaccinations. General discussion ensued and several speakers called attention to a letter by "Public Vaccinator" which had appeared in the *British Medical Journal* urging that public vaccinators, private practitioners, and vaccination officers should cordially coöperate to make the best of the "tremendous experiment" under the new Act in order that a fair trial could be given to it. Opinion was freely expressed that this suggestion should be adopted, as far as vaccination officers were concerned, in order that the period of five years during which the Act will remain in force should not be wasted from the point of view of experience. The following resolutions were unanimously adopted:—"That the best thanks of this association be tendered to the London and District Poor-law Officers Association for the valuable assistance they had rendered to the vaccination officers in the critical time through which that branch of the Poor-law service had been passing"; "That in view of the disparity between the salaries of public vaccinators and vaccination officers this association trusts that boards of guardians will adopt the scale of the former for the remuneration of the latter, as the responsibilities and duties of vaccination officers were greatly increased under the new regulation"; and "That this association be extended to form a National Vaccination Officers Association."—Mr. C. O. Elkerton intimated that he would resign the honorary secretaryship and it was arranged that a testimonial committee be formed to arrange for a suitable recognition of his twenty years' service as the honorary secretary of the association.

THE LEWIS CARROLL COT.—Mr. John Murray, vice-president of the Committee of Management of the Hospital for Sick Children, Great Ormond-street, Bloomsbury, presided at a meeting at the hospital on Friday, Oct. 28th, at which the subscribers to the Lewis Carroll Memorial Cot presented to the committee a cheque for £1000 "to endow the cot for ever."

THE FLANNEL-SHIRT CLUB.—The Flannel-shirt Club, of which the Countess of Strafford is president and Mrs. W. H. Courtney vice-president, has already distributed nearly 700 flannel-shirts to patients discharged from the medical wards of general hospitals in the metropolis. The shirts are bestowed exclusively upon necessitous working men who require warm clothing on returning to work after serious illness, exchanging the shelter and comfort of the hospital for exposure in inclement weather and other hardships. The club, which was only started last year, has 183 members, but many more are needed to enable it to adequately carry out its objects. Subscriptions and donations should be sent to the honorary treasurer, Mrs. Clutton, 2, Portland-place, W.

UNIVERSITY COLLEGE OF WALES.—On Oct. 26th Sir William Harcourt opened the new central block of the University College of Wales, Aberystwyth, which has been erected at a cost of about £20,000 and to which he, when Chancellor of the Exchequer, gave a grant of £10,000. In the course of an eloquent speech Sir William Harcourt dwelt upon the backward state of English education, especially the lack of a secondary system, and hoped that this Parliament would give England what Wales possessed—a sound system of intermediate education. He then attended the annual meeting of the Court of Governors of the College and there received a motion of welcome. Mr. A. C. Humphreys-Owen, M.P., and Sir John Williams, Bart., M.D. Lond., were elected joint treasurers of the College.

UNIVERSITY COLLEGE, LIVERPOOL.—At a meeting of the Council of the College on Nov. 1st, donations were announced amounting to £13,000 towards the erection of anatomical laboratories and the further extension of the medical school. Plans for the construction of the anatomical laboratories will be prepared forthwith.—Mr. Henry Briggs, M.B. Edin., F.R.C.S. Eng., has been appointed Professor of Midwifery and Gynæcology in place of the late Dr. John Wallace. Dr. Briggs has had a long experience as a teacher, having held the posts of demonstrator of anatomy, demonstrator of surgery, and surgical tutor in the medical school. He was for ten years honorary medical officer to the Liverpool Ladies' Charity and Lying-in Hospital, and for the past eleven years has held the post of gynæcological surgeon to the Hospital for Women, Shaw-street.

PRESENTATIONS TO MEDICAL MEN. — Mr. Alexander Lewers, L.R.C.P. Lond., M.R.C.S. Eng., of Creswick, Victoria, Australia, has been the recipient of an illuminated address from the local medical union prior to his leaving for England.—Mr. T. H. Champ, M.D. Lond., M.R.C.S. Eng., of Beaconsfield, Tasmania, was entertained on August 25th at a social meeting of the inhabitants of the district and presented with three addresses and a purse of sovereigns on the occasion of his leaving the district.—Mr. Geo. E. Rennie, M.D. Lond., M.R.C.S. Eng., of College-street, Sydney, New South Wales, was the recipient on Sept. 6th and 15th of a purse of sovereigns and an illuminated address from the members of the New South Wales Branch of the British Medical Association and the Sydney and Suburban Provident Medical Association, of which organisations he has been the highly esteemed honorary secretary for about three years. The occasion of the presentation was Dr. Rennie's leaving for England.—On the 27th ult. a large company of the inhabitants of Cruden assembled in the Drill Hall, Hatton, to present Mr. A. G. Duguid, M.B., C.M. Aberd., and Mrs. Duguid, with tokens of esteem previously to their leaving the district. For the last fourteen years Dr. Duguid has been the medical practitioner of the parish, an active member of the School Board, and an energetic member of the local volunteer corps. The presentations consisted of an illuminated address and a

Digitized by Google

purse of sovereigns to Dr. Duguid, while Mrs. Duguid was the recipient of a tea and coffee service. On the silver service is the inscription—"Presented to Mrs. Duguid, along with an address and purse of sovereigns to Dr. Duguid, on the occasion of their leaving Cruden, 28th October, 1898."

ST. GEORGE'S HOSPITAL MEDICAL SCHOOL.—The Duke of Westminster, accompanied by the Duchess, attended St. George's Hospital, Hyde-park-corner, on Saturday last, Oct. 29th, and distributed the prizes obtained by the students of the medical school during the past year. The following is the list of the Exhibitioners and Prizemen: Beaumont Percival, the Brackenbury Prize in Medicine; Harold Shuttleworth Barwell, the Brackenbury Prize in Surgery; Harold Robert Dacre Spitta, the Webb Prize in Bacteriology; Ralph Bignell Ainsworth, the Treasurer's Prize and Sir Benjamin Brodie's Prize. Notes, Short Comments, and Answers to Correspondents.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only, AND, WHEN ACCOMPANIED BY BLOCKS, IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

THE IRELAND FUND: A LETTER OF THANKS.

WE publish the following letter with pleasure:—"Mrs. John Ireland and Mrs. Stanley Brown beg to acknowledge with many thanks the great kindness of the proprietors of THE LANCET and other donors to the fund for the Misses Ireland (daughters of a medical man). The fund was closed last September; it amounts to £215 4*s*. On Sept. 27th an annuity was purchased with £100 producing £8 per annum. The other £100 is deposited in the Queen Victoria-street Building Society at 4 per cent., where it will remain till Miss J. J. Ireland attains the age of sixty years, when it will be withdrawn to purchase a joint annuity of £6 per annum."

"WANTED DIAGNOSIS AND TREATMENT."

To the Editors of THE LANCET.

SIRS,—Your correspondent, "L. M.," who wrote in THE LANCET of Sept. 24th under the above heading, suffers from what I—also at his age—suffer, and fortunate he is that his forced abstention from work is of one day and not three. I believe that the stomach in my case is at such times flaccid and dilated, that I suffer from inertia and ectasia, and that this is passing, for in the interval appetite and digestion are good. A distinct splash can be elicited, especially on those occasions when fluid is in the stomach and, I regret to say, often at other times after a fluid meal, but rarely, I believe, unless I am headachy—i.e., threatened with an attack. The pathology of this thing has come to be, to my mind, "neurasthenia." The attacks are precipitated often by a railway journey, and I have found of late that a course of resisted exercises—self-resisted, such as have been described in your volumes so often as a part of the Nauheim treatment for certain diseases of the heart—has seemed to render me more resistant, to lengthen the interval and shorten the duration of the attacks. I would also mention that I have for years taken every morning on rising, and I believe with benefit, a very hot sponge or shower bath of, say, one minute, followed by a decidedly cold shower lasting as long as in my judgment it may, and I come out of it with good reaction and without chill. Drugs I have found useless. Such a bath taken when the attack is threatened in early morning and followed by abstinence for a few hours will often succeed in warding it off. Fluids should be taboo at meals unless mere sips. Let the fluid ingestion be done an hour or two before meals and be of good cool water. In my own case a scantiness of urine an an inactivity of the bowels are further indications of the gastrectasic tendency and the weak absorptive power of the stomach.

I am, Sirs, yours faithfully,
October, 1898. G. C. L

A MICROBE-PROOF HOUSE.

WE extract the following from the *Leeds Hospital Magazine*:—

"The oddest domicile on earth is that recently erected at Yokohama by an eminent German bacteriologist. It is a microbe-proof house, built of glass blocks. There are no window-sashes and the doors, when closed, are air-tight. The air-supply is forced into the room through a pipe and filtered through cotton-wool to cleanse it of bacteria. To ensure further sterilisation the air is driven against a glycerine-coated plate of glass, which captures all the microbes the wool spares. The few microbes brought into the house in the clothes of visitors soon die in the warm sunlight with which the house is flooded. The space between the glass blocks, of which the house is built, is filled with a solution of salts which absorbs the heat of the sun, so that the rooms are much cooler than those protected by the thickest shades. In the evening the interior is heated by the salts radiating the heat they have absorbed during the day."

DIFFICULTIES UNDER THE INFECTIOUS DISEASES NOTIFICATION ACT.

To the Editors of THE LANCET.

SIRS,—I was recently called to see a child suffering from diphtheria and notified the case forthwith. On my next seeing the child I found the patient much worse and I gave an unfavourable prognosis. At the same time I learnt that the medical officer of health had called and expressed doubts as to the correctness of my diagnosis and suggested that the child was suffering from bronchitis. The following day I received a letter from the father dispensing with my further services and informing me that the medical officer of health had undertaken the case himself. I learnt subsequently that the child soon died and that the cause of death was certified by the medical officer of health to be diphtheria. I should be glad if you would comment on the above case, and any suggestions by which I might obtain redress would be most thankfully received by,

Yours faithfully,
D.P.H. LOND.

To the Editors of THE LANCET.

SIRS,—The following are the facts of a case which occurred in my practice during the week and I shall be glad to have your opinion as to whether the medical officer of health was within his rights or not.

I have a case under observation, but not yet reported, of suspected typhoid fever. The medical officer of health, having heard of the case, called at the house and asked to be allowed to examine the patient. This the mother of the patient would not allow, as she told him she had a medical man of her own in attendance. I have had no communication from the medical officer of health of his having tried to visit the patient, but learned the above facts from the mother of the patient next day.

I am, Sirs, yours faithfully,
Oct. 29th, 1898. SCOTLAND.

*** We recommend our correspondents to read our pamphlet entitled, "Difficulties under the Infectious Diseases Notification Act." It is unfortunate, but inevitable, that the provisions of the Act occasionally place the official in a difficult position with regard to the private practitioner. We can only advocate mutual forbearance. "D.P.H. Lond." should send a full account of the case, properly substantiated, to the Local Government Board. "Scotland," we think, should write to the medical officer of health offering to give him assistance and to see the patient with him if he is in doubt as to the diagnosis.—ED. L.

"A PLAN AND PLEA FOR NATIONAL MEDICINE."

WE have received a pamphlet bearing the above title. The author is E. L. Garbett, of the Peculiar People. Mr. Garbett's works cover a wide range. For instance, he has written a paper, which costs 3*d*., entitled "Bishops in Victoria's Time Only Idolaters," and another rejoicing in the name, "3130 Grounds for Holding that Satan Inspires Our Clergy." This latter can be obtained for the sum of 1*d*. "A Plan and Plea for National Medicine" starts on the assumption that "we can see nothing but a work of the devil in the way they [i.e., surgeons] have been paid hitherto

Digitized by Google

in Christendom." This is a statement with which many a hard worked medical man will cordially agree. Mr. Garbett's method for obviating these painful circumstances is not very clear, but as far as we can understand it is as follows: there is to be an ante-natal tax upon births, which will bring in £360,924 per annum. This sum divided among all the medical men in the British Isles would give every practitioner £463 per annum nearly. Mr. Garbett does not approve of Christian Science, for he says Mrs. Eddy exhibits a painful ignorance of the true meaning of 666, a fact which, "in my opinion, utterly demolishes their claims." Should any of our readers feel inclined to study this production further it can be obtained from William Reeves, 185, Fleet-street, for the small sum of 3*d*.

ENTERIC FEVER SPREAD BY A POTATO-SALAD.

FOR the following somewhat remarkable story a French newspaper named *l'Evénement* is responsible. A battalion of infantry quartered at Saarbruck having been decimated by enteric fever Dr. von Coler, the medical inspector-general of the division, was ordered to investigate the matter and if possible ascertain the cause of the epidemic. He accordingly made a close inquiry and at length came to the conclusion that the disease was due to a potato-salad. It seems that in honour of some festival or other the soldiers of the infected battalion were treated to this salad, which probably was more succulent than its name indicates, and that the preparation of the dish was entrusted to a man who had not taken the ordinary precaution of washing his hands beforehand, although (curiously enough) it had just been another part of his duty to empty a latrine bucket. The whole of the men who partook of the poisonous compound, to the number of 300, are said to have fallen ill soon afterwards, whereas their comrades on leave that day, and also the non-commissioned officers who messed apart, remained perfectly well.

LEPERS IN HAMBURG.

AT a meeting of the Hamburg Medical Society held on March 1st and reported in the *Deutsche Medicinische Wochenschrift* of Oct. 27th, Dr. Reincke said that 17 lepers (15 men and 2 women) have been discovered in the town since the first inquiry made in 1896. Of these 11 incurred the disease in Brazil, 2 in Honolulu, and 1 each in Surinam, Mexico, Penang, and the Philippine Islands. 8 were born in Germany, 4 in Portugal, 2 in Brazil, and 1 each in Mexico, Sumatra, and England. Since the inquiry 3 have died, 4 have left Hamburg, and no fresh case has arrived. An increase in the number is not probable at present, as patients are attracted by Dr. Carasquilla's serum treatment in Bogota. The regulations relative to lepers include compulsory notification and supervision by the medical officer of health, who has to visit them half-yearly in company with the medical man who attends them. Lepers may mingle with the public as long as the symptoms are mild and there are no discharges containing bacilli. In other cases they must either enter a leper hospital or submit to a number of restrictions in their own homes.

ROENTGEN RAY SCREENS.

MR. HENRY A. KENT, of 59, Myddelton-road, Bowes-park, N., writes: – "The use of a screen in some operations, such, for example, as bullet-extracting, has many advantages. It, however, occurred to me that a more simple and effective method might be the following. The mineral 'Willimite' crushed and passed through a 90 or 100 hole sieve gives a powder which is fairly good for screen work. This powder should be mixed with gum-water and glycerine (or any antiseptic medium) into a paint about the consistency of cream. By painting the parts under operation very good definition is thus obtained."

ANTI-VIVISECTIONISTS AT BRADFORD.

DURING the progress of the Church Congress at Bradford the Church Anti-vivisection League held a meeting upon which we commented in our issue of Oct. 15th. In our annotation, which was headed "Anti-vivisectionists at Bradford," we said that we had applied to Miss A. L. Woodward, whom we wrongly called the Secretary, she being as a fact the Honorary Assistant Secretary, for information as to the objects of the League; that we had received no reply, and that therefore we thought the Church Anti-vivisection League must be one of the secret societies in the Church recently mentioned in the *Times*. Since the publication of these remarks Miss A. L. Woodward has sent us the reports of the League from 1894 to 1898, some quotations from Cornelius a Lapide, a leaflet called "The Ethics of Vivisection" by the Rev. T. P. Ring, and a lecture called "Man's Relation to the Lower Animals Viewed from the Christian Standpoint." The author's name is not given, but the lecture is published by the League. Our view of the unsound attitude of the League has undergone no change, but we are quite ready to allow that it is not a secret society.

"THE EXCLUSION OF INFECTION FROM SCHOOLS."

A CORRESPONDENT signing himself "A True Briton," and referring to a letter under the above title which appeared in THE LANCET of Oct. 15th, informs us that he has known of cases where in consequence of proprietary schoolmasters letting their houses during the vacations the tenants introduced the infection of "mumps, scarlet fever, measles, whatnot," and the pupils returning at the beginning of the school term contracted these diseases through that unsuspected channel.

A STOUT NEGRESS.

THE *Philadelphia Polyclinic* of Sept. 17th states that Mrs. Mary Mazique, said to be the largest coloured woman in the world, died at Little Rock, Arkansas, on Sept. 7th, aged thirty years. She is said to have weighed at one time over 700 lb., or 50 st., and at the time of her death, 560 lb.

"BARKOO ROT."

To the Editors of THE LANCET.

SIRS,—Allow me to supplement Mr. Eustace Barton's letter in THE LANCET of Oct. 29th on Barcoo rot. During many years residence in Queensland I necessarily saw much of this complaint. Mr. Barton's description coincides with my own observations, but I am quite sure that it is not a constitutional affection, but a purely local one. Certainly local remedies applied in the usual way have no influence on the progress of the disease for the simple reason that on account of the thick scabbing they fail to reach its seat. If, however, Volkmann's spoon be freely used until healthy vascular tissue is reached any mild antiseptic will effect a cure in a few days. Of course, many of these patients are run down and suffering from want of proper diet, &c., and for such no doubt iron is an excellent remedy. The majority, however, are otherwise perfectly healthy.

I am, Sirs, yours faithfully,
F. E. HARE, M.D.,
Oct. 31st, 1898. Late Resident Medical Officer, Brisbane Hospital.

Izal (Banbury).—Each procedure is correct, but a combination of the two would not come well from one person. As L.S.A. he has qualified in medicine; possessing the M.R.C.S. he does not need to append any other diploma to his name when signing it officially; but if he desires to announce to the public that he has a medical qualification, why conceal the source of his qualification? An L.S.A. is not, in our opinion, entitled to call himself a physician.

A. G. S.—(1) As a rule, No. Attendance at particular classes might be allowed to count, but the matter would be one for the Dean of the British medical school and perhaps the General Medical Council to decide upon. (2) A list of the registrable degrees will be found in the Medical Register, as well as the conditions under which they are registrable. Only persons whose names are on the Register have a legal status as practitioners.

Dr. Alexander Wallace.—Some of the points alluded to by our correspondent were certainly before the jury. We do not think the justice of the verdict can be questioned, and the convict has now been reprieved.

Puzzled.—The lady should apply to the Royal Pharmaceutical Society.

Volunteer.—The method of style we have adopted is correct.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

METEOROLOGICAL READINGS.

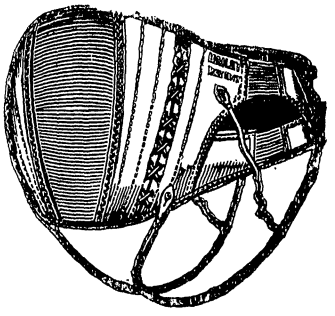
BAILEY'S PATENT ABDOMINAL BELTS.

For General Support, Pregnancy, Prolapsus Uteri, Umbilical Hernia, Uterine Support, Laparotomy, Floating Kidney.

FOR GENERAL SUPPORT.

Over 15,000 of these Belts have been sold. The only ones which will not ruck up.

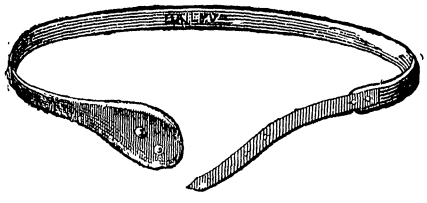


No Belt which is cut in one piece can give efficient support to the abdominal walls without undue pressure on the hips.

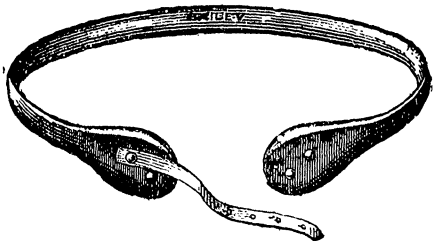
They are so constructed that the part which surrounds the abdomen is distinct from that which surrounds the hips, so that each part can be adjusted properly, and as the size of the hips varies very much in different persons, this is a matter of the first importance.

The Greatest Improvement ever Effected.

Attested by hundreds of unsolicited Testimonials from eminent Members of the Medical Profession and others.



FOR PREGNANCY.



SPECIAL DEPARTMENT FOR LADIES. 18/-, 25/-, 35/-, 45/-; *usual Discount.*

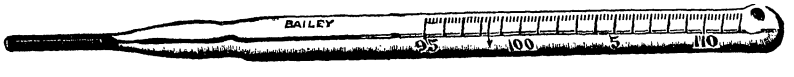
All Belts are made and fitted on the Premises. Or competent assistants sent to measure.

BAILEY'S WASHABLE TRUSSES.

"NO GOOD RESULTS CAN BE OBTAINED FROM ANY TRUSS WHILE THE DAILY BATH IS TAKEN WITHOUT ONE. TO EFFECT A CURE THE RUPTURE MUST NEVER BE ALLOWED TO COME DOWN."

THIS can be effected by wearing one of Bailey's Washable Trusses, which, as they do not absorb any moisture, require no drying. They can be worn also as an ordinary truss, so that for sea-bathing it is not necessary to carry a duplicate.

They are covered in a strong, flexible, and very durable enamel, which will last for years, and are therefore especially suitable for the bath, for travellers, for sea voyages, and the tropics. There is nothing to wear out as in the ordinary leather-covered trusses, and they are unaffected by moisture or perspiration.



Anticipating a large sale for these Trusses, we have fixed the prices as low as possible.

For measurement, send the circumference of the pelvis two inches below the crest of hip bone, and state right left, or double.

Single, each 10s. 6d. Double, each 15s.

That Medical Man is yet to be found who after investigation and trial fails to fully endorse the claims made for

FELS'S GERMICIDE SOAP.

Nearly three thousand letters of approval have been received from the Medical Profession of Great Britain, showing that in Obstetrics, most forms of Skin Diseases, in Dental Practice, as a Germicide, as a Deodorant, and in numerous other uses, including the Toilet,

FELS'S GERMICIDE SOAP

stands alone.

It contains HYDRARG. BICHLORID., SAL. ALEMBROTH, B. NAPHTHOL, and EUCALYPTOL.

Every Physician who tests it believes in it.

Every modern Chemist stocks it and sells it at protected prices.

All Wholesale Houses supply it.

1/- per CAKE; 8/4 per Dozen.

The Bradshaw Lecture

ON

MYXŒDEMA AND ALLIED DISORDERS.

Delivered before the Royal College of Physicians of London on Nov. 10th, 1898,

By WILLIAM M. ORD, M.D., F.R.C.P. Lond.,
PHYSICIAN TO, AND LECTURER ON MEDICINE AT, ST. THOMAS'S HOSPITAL.

MR. PRESIDENT AND GENTLEMEN,—The pathology of myxœdema, so far as it is at present known, will doubtless form a part of the lectures which Dr. George R. Murray of Newcastle will deliver before this College next year. In the present lecture I propose to devote my attention mainly to the clinical aspect of myxœdema, its recognition, its differential diagnosis, and its treatment.

Diagnosis.—The primary diagnosis of the disease is not always so easy as might be expected from the observation of well-pronounced or typical cases. This is true, indeed, of all kinds and manner of disease. Whatever be the disease it is necessary, in the first place, whether we do it consciously or not, to construct a picture of such disease in its full development, including, first, the main and most important symptoms, then, next, the less frequent and less characteristic symptoms, and, thirdly, accessory symptoms of varying value in various cases. Such a picture cannot be constructed by making a mere list of symptoms. It is necessary, by careful comparison of a considerable number of cases, and also by bestowing careful regard on the relations of symptoms to etiology, to make the picture a carefully shaded one—to put into strong relief that which is most important, and that which is less and less important further and further in the background. The picture must, in a word, have its perspective and its colouring carefully drawn and filled in. Such a process, carried on in a more or less methodical manner, must be applied to the separation in our minds of diseases and of their subjects from one another before we are able to write down the primary naming of any disease of which there may often be many forms. As the knowledge of myxœdema grows by the addition of new cases to our original list it becomes evident that around our well-defined picture are to be found forms more or less obscure, in part because of incomplete development of the whole series of symptoms and in part also by reason of curious modifications of myxœdema constituting alliances with diseases to which the term "myxœdema" cannot with propriety be applied.

Classification of symptoms.—Let us now endeavour to make a classified list of the signs and symptoms of myxœdema. The first lines which we draw in firmly in limning the disease are those connected with the external appearance of patients, such as the increase in the size and bulk of the whole body, due, evidently, in part to changes in the skin, in part to changes in the subcutaneous tissue. Next, the changes in the skin affecting more or less the whole surface and determining changes in the appendages of the skin, in the hairs, in the glands, and in the organs of touch. In correlation with the changes in the skin we have to take note also of altered states of mucous membranes resembling those observed in the skin and leading again to destruction of appendages, such as the teeth and glandular structures. It is here a point of much importance to remember that the swelling of the skin and mucous membranes is not an ordinary dropsical swelling, does not in any way gravitate from the upper parts of the body to the lower, and does not in any part pit on digital pressure but is firm and resilient. Next comes a group of symptoms indicating in various ways impairment of the functions of the nervous system; such as slowness in muscular movement and tardiness in response to impressions made upon the surface of the body, slowness in thought and action, weakening of memory, disturbance of the balance of muscular actions in the limbs. With these we must associate the quality of the speech and the sound of the voice perfectly typical of the disease and dependent apparently on the combined effects of the swelling of the lips and fauces, of failure of the movements of the muscles within the swelling, and of default of nervous power in controlling the action of muscles. Further, beyond the above-mentioned signs of dilapidation we may find various degrees and kinds of mental aberration and certain mental phenomena which may be fairly called "peculiar" up to a certain point.

Symptoms of the second degree.—The next in the rank of important signs may, I think, fairly be taken to be the lowering of the temperature of the body—rarely, if ever, absent when the disease is fully pronounced. A less common symptom than those already enumerated is the tendency to hæmorrhage following comparatively slight injury, the hæmorrhage being most commonly in the skin or mucous membrane, but sometimes in internal organs. Partly with special regard to etiology we have to consider the question of sex, noting that the affection is very predominantly one of the adult female. In all diagnoses negatives have to be marshalled among sources of help. We shall find that there is no affection of the viscera which can be called characteristic of myxœdema, although in the course of the disease visceral affections may arise, chiefly from the operation of external and new causes, not wearing, so to speak, the uniform of the higher groups. After passing in review the components of the several groups of symptoms and conditions above classified, the relations of the thyroid body assume great importance, seeing that certain changes in that body and its functions are in effect causative of myxœdema. Another set of changes belong to other diseases which in this aspect have some sort of alliance with it and help us to its explanation. We may now amplify the elements of each group of symptoms in succession.

Details of symptoms.—The often vast and quivering bulk of the body is, I have already said, partly brought about by alteration in the skin and partly by developments of fat beneath the skin. It is doubtless often also due in part to alterations in the muscles and viscera, all partaking of the nature of the change most readily noticeable in the skin. The skin is found to be everywhere dry and often in many parts is clearly very much thickened in its epithelial layer as well as in the derm. It is exceedingly rough and harsh to the touch, so that, as a patient once remarked, you might almost strike a match upon it—an experiment which, I may say, I have never yet attempted. The varying connexions of the skin with the deeper tissues involve considerable variety in the appearance of the swollen parts. For instance, the loss of natural expression is at once forced upon one's notice. The skin on the checks and forehead is very obviously translucent, dry and firm to the touch, but not nearly so harsh to the rubbing touch as elsewhere. Both upper and lower eyelids are much swollen and the upper lids droop heavily over the eyeballs. They are almost transparent and look at first sight like the eyelids of persons suffering from acute renal disease, but they do not in the least present any pitting on pressure. As a result of the drooping of the upper eyelids the eyebrows are mostly raised in various degrees, sometimes to a very considerable extent, by the effort to elevate the upper lids above the level of the pupils. The alæ nasi are generally particularly thickened and translucent, giving rise to a broadening of the whole nose. The upper and lower lips alike are so swollen as to destroy the natural expression of the mouth and to reduce it to little more than a chasm between the inflexible margins. The ears are usually both very much enlarged and thickened. The total effect is that of a mask of sorrowful immobility. There is in this a remarkable resemblance of myxœdematous patients one to the other.

In examining the body one of course generally takes note at once of the condition of the thyroid body, although this has no direct relation to the state of the skin. On each side of the neck above the clavicles are usually found large soft projections. Sometimes they are called "dough-like," but they are not plastic like dough and convey to the touch the same kind of sensation which might be yielded by a large ripe tomato imbedded beneath the skin. These projections, as you know, are partly fat, partly changed connective tissue, and possibly in part veins. They are, as you know, also very characteristic of that modification of myxœdema which is observed in sporadic cretinism. The abdomen is usually particularly large and often pendulous. In the hands and feet, most noticeably in the former, the changes in the skin determine a great thickening and coarsening of these members. In the hand the digits while swollen are much flattened out and when the hand is

Digitized by Google

extended no spaces separate one finger from another. The resulting conformation of the hands has been aptly called by the late Sir William Gull "spade-like." The altered hands lose, like the face, what we may call the natural expression, and lose also their delicacy of movement. Among the earliest manifestations of the disease is a change in the hair, which becomes rough, loses its natural lustre, and breaks very readily, becoming after a time very ragged and very intractable in the toilet. The hair thus altered speedily falls off both from the head and from the eyebrows—not before, however, the latter, if well developed, have passed through a stage of raggedness which is brought into prominence by their raised position. The eyelashes undergo similar disfiguration, are always much broken, and often are lost altogether. The hair over the body also dwindles and falls off, and the nails, although they rarely go so far as to complete atrophy, are wasted and brittle. It is, perhaps, mostly in the hands and feet that the extreme roughness of the skin is most developed; the highest degree of this change occurring on the sole and the heel.

Mucous membranes.—All visible mucous membranes exhibit alterations parallel with those of the skin. In the mouth it is evident that the swelling of the lips is very much compounded of mucous membrane. The cheeks project in between the teeth, are marked by them, and are very apt to be bitten. The tongue is very large and generally very anæmic. In the fauces we can see the changes of mucous membrane generally most pronounced. The uvula and soft palate press down upon the tongue as a somewhat firm, very translucent, and imperfectly moveable mass. Similar changes may be seen in the vulva and vagina. The teeth almost invariably undergo impairment of nutrition, sometimes becoming brittle and falling to pieces and sometimes coming out whole without much obvious alteration in structure. The gums are usually greatly swollen and yet recede from the teeth, tending to become ulcerated and to bleed on the very slightest provocation. The most obvious explanation of the decay of the hair and teeth and of the dryness of the skin is to be found in an extreme swelling of and change in the connective tissue in the skin and mucous membranes. The connective tissue becomes firm and resistant, ultimately encroaching on the pulp of the teeth, on the follicles of the hairs, and on the sebaceous and sudoriparous glands. Whether these changes in the connective tissue be in part of neurotrophic origin is a question to be considered, but at present not fully capable of answer. It is important, however, to know that under certain treatment, hereafter to be set forth, the skin, losing its swollen character, resumes its functional activity, and the hair frequently returns also in a healthy form over what have appeared to be bald surfaces. The swelling of the body is, however, not always uniform or constant. It may and usually does appear most strongly in the face and supra-clavicular regions. It may, however, be found in the limbs or in the abdomen before involving the face and neck. It may in early stages disappear altogether for a time, or it may be transferred from one region to another. The face is particularly subject to alterations in the amount of swelling, generally in association with changes in symptoms, more especially nervous symptoms—disappearance being followed by headache or neuralgia and recurrence by relief of these conditions.

Nervous and muscular changes.—Tactile sensation all over the body is in typical cases diminished. This can doubtless be explained in part by the alteration of the connective tissue in and around nerve-endings, but it is also in some cases clearly traceable to defect in the central receiving nervous system. The defect of sensation is, of course, particularly noticeable in parts which depend for much of their usefulness upon very delicate and sensitive nerves. The fingers notably lose not only mobility but also accurate sense of touch, which is very plainly demonstrated when a patient endeavours to fasten or unfasten a button or pick up a pin from the floor. There is also a tendency to drop things held in the hand. Not only, however, is the sense of touch blunted, but the recognition by the central perceptive organs of impressions made upon the periphery is distinctly retarded. In certain circumstances the skin entirely loses sensibility in parts. A lady whom I have seen recently and who presents fairly typical myxœdema has from time to time sudden increase in the swelling of the feet and hands, accompanied by a complete loss of sensation over restricted areas of no particular form. When, as happens from time to time, the swelling passes away sensation is restored to the same condition as in the rest of the body. We may find, therefore, both bradæsthesia and anæsthesia in myxœdema. The special senses are sometimes affected, particularly the sense of smell and the sense of taste, offensive odours being complained of where no signs of such odours appear to be present and tastes of excessive sweetness or acidity or bitterness—most commonly the sweetness—being present in the mouth.

As regards the muscular system, there is in all cases a marked debility and tendency to ready exhaustion by exertion, sustained action of muscles evidently using up their power very rapidly. The complaint of excessive muscular weariness is one of the next which we have to listen to, and sometimes the failure of muscles leads to very distressing results. Patients sometimes are unable to keep the head erect. For the most part, both in the erect and sitting posture, the head falls forward with the chin on the upper part of the chest and cannot be restored to its proper position without assistance from the hands either of the patient or of a nurse. Sometimes the head, when restored to its position or a little beyond the proper position falls backward with a rapid movement enough to cause anxiety as to the occurrence of injury consequent upon the jerk. Such loss of balance in the movements of the muscles supporting the head seems to exist throughout the whole system and is readily noticed in the gait of well-marked cases. I have seen this most often of course in women, who are the most frequent victims of the disease. If asked to walk they rise from the sitting to the erect posture with a somewhat tremulous effort; they sway somewhat in standing, and in walking present a quivering of all the muscles of the body, particularly of the legs, with each step. Their movement in walking is such as might be expected to attend great nervous excitement with difficulty to restrain it, and is not altogether without a suggestion of stateliness, such as might be represented upon the stage. Not infrequently the want of coördination in flexors and extensors which leads to this quivering movement goes so far as to determine sudden falls, not caused by the feet coming in contact with obstacles, but by giving way of the knees. The patient falls suddenly into a kneeling position and often experiences serious injury, sometimes even incurring fracture of the patella. This form of nerve weakness may persist even after the disappearance of the main symptoms already noted.

The speech of the myxœdematous patient is, so far as I know, unlike any other modification of speech in disease. There is an obvious difficulty, in the first place, in getting words out of the mouth. They seem to stick at the lips and their ultimate pronunciation is accompanied by either a writhing of the upper lip or by a puffing, explosive jerk of the word through the chasm between the comparatively immoveable lips of the patient with advanced disease. The quality of the voice is nasal and leathery, the tone is monotonous, and at the same time speech is frequently interrupted by little explosions through the nostrils. The words uttered, although somewhat blurred, are usually correctly framed and, for the most part, accurately represent what is in the mind. Sometimes, however, patients still state that they have words in their mind which they are unable to put into speech. In spite of the slowness and painfulness of utterance the patients are disposed to talk at great length. Once started in conversation they tend to go on indefinitely. I have known a patient talk continuously for an hour or even more without interruption save for drawing the breath at frequent intervals and without taking apparent notice of a remark or question intended to break the prolonged monologue. In connexion with speech it must be remarked that the patients in many cases write letters also at great length, and that as a rule the handwriting is good and monotonously regular, the difficulties already mentioned in respect of the movements of the fingers not appearing to interfere with the use of pen or pencil. The voice, which I have tried to describe, with its monotonous flow and leathery intonation, is, once heard, almost in itself a ground for diagnosis of the whole disease. It has occurred to me to hear a patient speak outside the door of my consulting-room and to recognise the disease before I had actually seen the subject. It has occurred also under my observation that patients in hospital under treatment for myxœdema would detect in the voice of a newcomer the existence of the

Digitized by Google

malady and would say, "That's my disease." The imperfections in speech are not always so complete as in the typical cases which I have described. It sometimes happens that the elocution is only comparatively slow and the existence of a difficulty is fully understood only after treatment. Then it is frequently found that the patient naturally speaks very quickly and with excellent elocution, which has only been modified in a minor degree. It is, of course, obvious that not infrequently the loss of teeth complicates matters and increases the difficulty of articulation. If the treatment of myxœdema in any case be successful natural speech is gradually resumed, but while the mechanical obstacles appear to pass away completely the tendency to garrulity for the most part persists, so that the physician has still to listen to a long setting forth of comparatively small matter recited volubly and with interminable iteration. That the state of the nervous system is much concerned in this alteration of speech is, I think, abundantly clear. It is perhaps only the first to attract our notice of many nervous symptoms. In some cases to the difficulty of speaking a difficulty in swallowing is added. The swollen state of the fauces and of the mucous membrane beyond would make us ready to expect some difficulty, but at times dysphagia of considerable severity together with affection of inspiration will lead to a suspicion of affection of the medulla oblongata.

Changes in the mind.—It has been noted already that the aspect of the patients is lethargic. A considerable number are actually lethargic and unnaturally placid, but it is very common to find, even early in the disease, indication of the disturbance of mental equilibrium. The most common of all is the gradual development of a suspicious frame of mind. This is not, as a rule, a suspicion of conspiracy or of intent to do harm on the part of the people around the patient, but a constant idea that all such people regard the patient unfavourably and are finding fault. This may be developed so far as to make the patient actually violent and to cause him to protest against the injustice of the supposed attitude of the persons around; and I have seen patients so terrified by the sensation of dread of some ill-defined malignant influence that they have tried after getting out of bed to throw themselves from windows or down stairs. It is also interesting to observe that some people who are not suspicious of others are suspicious of themselves and spend their time in moaning over their sins and shortcomings, although these cannot be stated in any clear or definite form. Some years ago a patient under my care at St. Thomas's Hospital very well illustrated such conditions. She was a woman of more than middle height, was enormously swollen, and weighed over 20 st. She was afflicted particularly with *cacoëthes loquendi*, and was full of suspicions about everybody who had to deal with her as well as about the rest of the patients in the ward. They were all thinking evil of her and no one expressed any sympathy for her sufferings. When I paid my visits to the ward she often detained me for half an hour with the endless recapitulation of her sufferings, suspicions, and fears. One night, under the influence of great excitement, she actually fell out of bed, receiving, however, no obvious injury. One day, after I had been enduring her loquacity for some time, I was passing on to see another patient when she sat up and reviled me and all present on account of the want of interest shown in her. It occurred then to one of my clinical clerks to take an opportunity of letting her talk herself out. He sat by her bed and listened patiently to her as long as she was able to continue speaking. This lasted for more than an hour and a half. She immediately took a great fancy to him and said that for the first time she had been properly understood. This was before the days of the use of the thyroid treatment, but the patient certainly improved during a long stay in hospital and left weighing only 18 st. I attributed her improvement to prolonged rest in bed, the maintenance of warmth, and the use of jaborandi. A few months afterwards she appeared in the ward one afternoon during my visit. She was still further reduced in bulk, weighing then only about 15 st.; but, while she talked a great deal, her change of mental attitude was quite remarkable. She, indeed, came mainly to apologise to me and to the nursing staff for her rudeness during her stay in hospital. She had known all the time that she was rude and unreasonable, but she was quite unable to repress the feelings which prompted her to rudeness. The case was valuable as illustrating the licence in which persons of unsound mind will sometimes indulge, being fully aware at the time that their conduct is unjustifiable. She did not make her appearance again in the hospital—at least, in my ward. Mental improvement following a distinct abatement of the signs of disease has been observed in this case as well as in some others. On the other hand, the suspicions and the garrulity often remain the last symptoms to be overcome. In fact, in some cases they are actually exaggerated in persons who have lost all the other characteristic signs of the malady.

In more than one case the mental disturbance has become so great as to require restraint. Taken in conjunction with alterations in the thyroid gland all the materials for a direct diagnosis of myxœdema are to be found among the foregoing symptoms, but there certainly are cases of myxœdema in which for one reason or another certain of the symptoms may be absent or modified. Thus, for instance, as Dr. George R. Murray has recently shown, instead of the marked swelling of the whole body, a relative tumefaction, accompanied by a yellowish tinge of the skin varying under treatment, would render the first-sight diagnosis a little obscure. The speech is often not characteristic, even when the other parts of the picture stand out well, and the hair and teeth may escape the ordinary degeneration. I have seen recently a woman whose hair at the age of sixty years was almost, if not quite, natural, being abundant in quantity, not having fallen out, and not being broken or ragged. The teeth, however, in this case had gone early. There are, indeed, cases in which it must be admitted that diagnosis is very difficult; cases in which, while the bulk of the body is very considerable and the face much swollen, the yellowish, transparent look of the skin is not present, the speech is but little impaired, and the hair and teeth have suffered only in a minor degree. Some of these cases are not easy to separate from cases of simple over-fatness of the body, and it is only by dint of repeated verification that the existence of symptoms belonging to myxœdema and not to simple fatness may be determined. In the early identification of myxœdema its subjects have much the appearance of being really victims of a form of Bright's disease without albuminuria, and, indeed, after some of the early publications of observations on myxœdema, it was seriously contended by more than one accomplished physician that the disease really was Bright's disease associated with an unusual form of dropsy. The compass of this lecture will not allow of my entering into the details of the controversy, but I think that no one nowadays has any doubt of the absolute difference between Bright's disease and its dropsy and myxœdema and the swelling belonging to it.

Associated symptoms.—We can now proceed to consider some of the associated symptoms of myxœdema, not of such primary importance as the preceding.

Temperature of the body.—First among these is the lowering of the temperature of the body. In the well-established disease the temperature of the body is usually lowered by from 1° to 3° F. Such lowering of temperature, however, is not by any means always present in the early stages. The heat of the body may be maintained at something like the average temperature or a little above it by the influence of intercurrent disease, particularly that of phthisis. Indeed, an average temperature, say of 94° or 96° observed in a case of well-developed myxœdema may be taken to be an indication of a sort of pyrexia calling for the most careful search for any local or general causes, such as in ordinary people raise the temperature to 100°, 101°, or more. It will be seen afterwards that one of the first effects of the successful treatment of myxœdema is the raising of the temperature. Related no doubt to the lowering of the temperature, we find patients liable to great suffering and aggravation of their symptoms during the prevalence of cold weather. This is certainly the rule, and one may notice in hospital how our old patients come back to us with the frosts. They do not appear so much to feel the cold as to be conscious of the injurious effects of cold. One may see a patient sitting up in bed and complaining of feeling ill because of the cold weather. The hands and feet will often be found then to be extremely cold and blue and yet it is far from uncommon to find the complaining person allowing her nightdress to be open so that the air directly impinges upon the skin, and careful questioning will elicit the fact that the patient is not conscious of such impact of cold air, the general numbing of sensation masking the effects of a prejudicial influence. Independent of various modes of treatment, climate must be regarded as very strongly modifying the progress of the

Digitized by Google

illness. The people who can have well-warmed houses and keep out the cold of our English climate pass through the winter with much less suffering and danger than poorer people unprovided with such protection. Still more, if people can exchange our English climate for a warmer one during the winter season the progress of the disease may be retarded and the sufferings greatly diminished. Observations of temperature must be made by insertion of a thermometer into the mouth or into the rectum. Axillary determinations may be regarded as practically valueless.

Hæmorrhages.—Hæmorrhages from various parts are, as we have noted, not uncommon in myxœdema, though far less general in their occurrence than the alteration in temperature. They occur mostly in the fully established disease. Epistaxis and bleeding from the gums will often be noted. The extraction of a tooth, often called for, is always to be dreaded on account of the hæmorrhage which is apt to follow, lasting in some cases for three or four days in spite of plugging and the use of styptics and involving a drain which the anæmic patient can with difficulty sustain. Hæmorrhages in the skin and from the bowels are less common, but uterine hæmorrhage is often a serious source of enfeeblement, becoming dangerous in association with parturition. Post-partum hæmorrhages are far from uncommon in even the early stages of the disease to an extent almost becoming a rule when the relatively small number of myxœdematous patients who become pregnant is considered. The most serious hæmorrhages are those into the brain. I have seen three cases of apoplexy in two of which post-mortem examination showed bleeding into the brain in the usual position of cerebral hæmorrhage, and in the third in a curiously distributed form in the cortex of the brain. In the last-mentioned case I had the opportunity of watching the progress of the patient for a considerable time. He was a man, aged thirty years, a waiter by occupation, and was admitted for the first time to St. Thomas's Hospital under my care on June 14th, 1892. It appeared that his illness commenced six years before his admission. He began at first to feel dull, heavy and depressed, and became clumsy, especially with his hands. His friends complained of his dull and muffled voice. All exertion became a trouble and he would occasionally fall. His abdomen and body generally began to swell and his face became round, puffy, and yellowish-brown with flushed cheeks, earning for him the nickname of "the fat boy in Pickwick," which replaced the nickname of "Skin and Buttons" which had before the illness been bestowed upon him on account of his pale and hollow-eyed countenance. His hair had begun to fall out some time before admission and his skin was always very dry. He stated that he was rather worse in the winter than in summer time and that he had lost interest in the outside world. He was conscious of being very irritable. At the time of admission his skin was exceedingly harsh and dry, also much pigmented; his hair was dry, scanty, and broken, particularly on the face and head. His features were heavy, his expression was somewhat fatuous, and there was a strong suggestion of his having undergone a sort of Mongolian change of physiognomy. He was very bulky; there was some fulness about the clavicles; the thyroid gland could be felt but was evidently smaller and firmer than natural. All his movements were sluggish, and his hands were spade-like, with impairment of the finer movements. There was no sign of visceral disease and the urine was normal. Glycerine extract of thyroid, prepared after the admirable method of Dr. George R. Murray of Newcastle, was injected hypodermically in doses of 15 minims on the following dates:—July 12th, 16th, 19th, 22nd, and 30th. He improved considerably under this treatment, which was, however, discontinued on account of great swelling and distress following the injections and was replaced by internal administration of the same preparation in the same doses daily. Under this treatment improvement continued to be rapid; his bulk diminished, his skin became moist, and at times he perspired very considerably. His hair grew again very quickly and in great thickness. A photograph presenting his condition after six weeks of treatment was taken for me by an exceedingly clever clinical clerk of mine, who wrote on the back of it the very appropriate quotation from the "Ingoldsby Legends":

> "He grew sleek and fat;
> In addition to that
> A new crop of feathers
> Came thick as a mat."

Only we must pass over the fact that the patient did not, like the jackdaw, get fatter. The patient left the hospital on August 28th, 1892, but continued to attend as an outpatient for some months afterwards, taking the glycerine extract regularly, but only now about twice a week. His attendance soon became irregular. He appeared to have taken up service as a waiter. I learned at the time that he was a very good waiter in a general way, but was somewhat expensive in consequence of a tendency to drop plates and dishes when he was handing them. It is certain, however, that at this time he began to indulge in alcoholic stimulants, and to have neglected his thyroid treatment. The signs of myxœdema gradually returned and at the beginning of July, 1895, he had a fit in which he lost consciousness for some hours and this was followed by a second and a third fit during that year. In the last of these the tongue was bitten. He was again admitted to St. Thomas's Hospital on Nov. 13th, 1895. Much of the appearance presented at the time of his first admission had now returned and his urine now was of a specific gravity of 1028, with a trace of albumin. Shortly after his admission he was seized with convulsions and was unconscious for one hour. On Nov. 14th he had two fits, after which he became very violent, struggling and talking incoherently. He sweated profusely all the next day and was still very violent, requiring restraint by a male attendant. He then became comatose for some hours and died on Nov. 16th. The temperature, which had been 98·2 at the time of his admission, rose on Nov. 13th to 100·6°. At the post-mortem examination the thyroid gland was found to be very small and flabby, the isthmus being little more than a strand of connective tissue. It is important to state that the adrenals were diseased, the left being increased in size by enlargement of the central cavity, which contained several calcareous and caseous nodules, some surrounded by miliary tubercles. The right adrenal showed a similar change, but with all this the mass of glandular tissue was unaffected; there was now no pigmentation of the skin. On examining the brain there could be seen through the arachnoid and pia mater innumerable minute hæmorrhages dusted, as it were, over both hemispheres, but more numerous on the left side. The cortical vessels were much distended and the brain throughout was hyperæmic, but there were no petechiæ below the surface. Otherwise the brain appeared to be healthy. As regards the hæmorrhages noted on the surface of the brain it must be remarked that in his convulsions and struggling he had evidently met with some injury of the scalp, but the distribution of the petechiæ and their superficial character were most probably either the result of his epileptic fits or the cause of them. It is well known that petechiæ occurring in the face of children are not unfrequently found to be the result of convulsions and that occasionally their existence may lead to the recognition of fits occurring during the night and not in the daytime.

Changes in the thyroid gland.—It is now generally admitted that myxœdema, in common with the sporadic cretinism of children and cachexia strumipriva, is dependent on a destruction or loss of the function of the thyroid gland and that in many ways myxœdema is allied to cretinism in which affections of the thyroid gland play an important part. It is commonly the case that in myxœdema diminution of the thyroid glands is recognised during life; not, however, always, by reason of the difficulty of feeling the thyroid through the massive and unyielding cutaneous tissue. For the most part the gland is found in a state of atrophy, having the secreting structure partially or completely destroyed by a fibrosis of connective tissue, there being also an associated loss of the colloid secretion. But it is not always a reduced thyroid that is found. In an enlarged gland the destruction of the tissue may be brought about by a new growth; and, furthermore, the history of a certain number of cases of myxœdema indicates that an enlargement of the gland has preceded its contraction and atrophy. To go further than this, it may be stated that in certain well-observed cases the symptoms presented before the establishment of myxœdema have been more or less the symptoms of exophthalmic goitre. It appears to me probable that we shall recognise in the future more and more the occurrence of a stage of hypertrophy of the thyroid gland, with or without the signs of Graves's disease, as an antecedent of myxœdema.

I will venture to give here an abstract in as short a form as possible of a case the notes of which have been kindly sent to me by Mr. Alex. Hope Walker of Cranleigh, whom I beg now to thank for his kindness. It is, of course, helpful to me to have the opportunity of quoting the cases

Digitized by Google

of other observers as well as my own. The patient was a woman, aged twenty-three years, living at Alfold in Sussex, a place where, according to Mr. Walker, goitres are frequent. Being hitherto in the enjoyment of fairly good health she noticed in July, 1890, that her neck was larger than usual, though neither pain nor inconvenience was experienced from the enlargement. In March, 1891, she began to present signs of exophthalmic goitre, and was subsequently admitted in June of that year to Charing-cross Hospital under the care of Dr. John Abercrombie. The diagnosis of exophthalmic goitre appears to have been formed and adopted at the hospital, where she was treated with iron, quinine, and digitalis, together with daily galvanisation of the thyroid. Under this treatment the swelling became reduced in a somewhat marked degree, and she left the hospital on August 1st, 1891, to all appearance cured. She then went into service at Burgess Hill and continued well until November, 1893, when she noticed her legs, arms, and hands to be swelling. She finally gave up her service and returned to Alfold, where she was seen by Mr. Walker on Nov. 20th, 1894. At that time, to quote Mr. Walker's notes, "the face throughout was markedly swollen, the skin feeling thick, looking translucent and waxy, and the eyelids were particularly swollen. The nose was broad, the lips were thickened and diverted, the face was devoid of all expression; the pink flush, so constantly present in these patients, was absent; the hands were spade-like; the skin was harsh, dry, and pale; the hair was falling out, the speech was slow and monotonous, the temper was sulky and uncertain, the movements of the body were all very slow and deliberate, the urine and the viscera appeared to be normal, the thyroid gland could just be felt." I think you will agree with me in accepting the first stage of this patient as one of exophthalmic goitre and the second as one of myxœdema. I may add that the treatment was mainly by the administration of thyroid in the form of tabloids. By the end of January, 1895, she appeared to be quite well, but being at home she neglected to send for her tabloids and drifted back into her myxœdematous condition. She was recovered from this once or twice by renewed treatment, but finally she died rather suddenly from heart failure on June 6th, 1897—that is to say, seven years after the first appearance of symptoms connected with the thyroid. No post-mortem examination was made so far as I am aware. It appears probable that the enlargement of the thyroid in such a case, as, indeed, in exophthalmic goitre generally, is due partly to hyperæmia and partly to changes in the gland which are apt in certain cases to determine proliferation of the epithelium surrounding the cells, such proliferation ending in the replacement of the true glandular structure by fibrous materials and consequent destruction of the functions of the gland. The gland being thus destroyed after a time undergoes a sort of cicatricial contraction, leading to atrophy comparable to that occurring in cirrhosis of the liver.

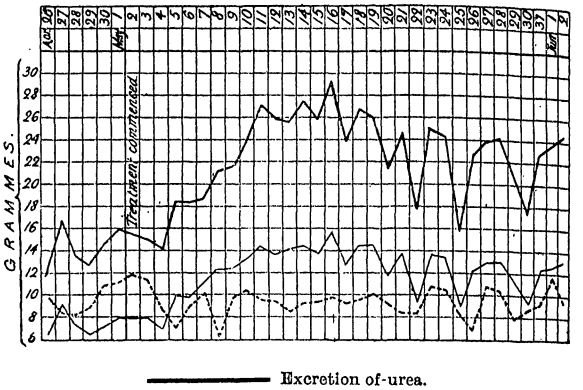
I am inclined to think that the succession of enlargement of the thyroid, with or without the typical signs of Graves's disease, is much more commonly an antecedent of myxœdema with contracted thyroid than is generally supposed. In my own experience, and probably in that of many other physicians, young women brought for treatment on account of anæmia and various nerve disorders are found much more commonly now than formerly to present some enlargement of the thyroid. Doubtless with the phenomena of myxœdema and exophthalmic goitre brought more and more prominently before our notice we have come to take more careful note than formerly of the state of the thyroid gland. It is certainly common to find a definite increase in the size of the gland present where neither the parents of the patient nor the patient herself were conscious of anything of the kind. I do not mean to say that in all these cases the enlargement of the thyroid is followed by atrophic change, but the great frequency of the occurrence of enlargement in adult women justifies the hypothesis that in a much larger number of cases than we know of at present an enlargement of the thyroid has preceded the development of myxœdema. How this enlargement comes about is certainly not well understood as yet, but it must be remembered that in the first place myxœdema, like exophthalmic goitre, is a disease affecting women in an exceedingly larger proportion than men. In fact, the title to Sir William Gull's first paper brings this predominance into strong relief. The title of the paper was "On a Cretinoid State supervening in Adult Life in Women." Temporary increases and diminutions of the size of the thyroid body are certainly not easy to recognise and determine, but certainly where a thyroid is once enlarged it is often found that there is increase of enlargement at the time of the menstrual period. When, as in many women, conditions approaching the inflammatory occur in various parts of the body at the time of menstruation it is no hasty induction if we suppose that a local exaggeration of such conditions may lead to a permanent enlargement, to be followed by simple subsidence or possibly in some cases by contraction. I know of no changes in the sexual organs of men in any way related with myxœdema where it attacks them and *primâ facie* I should not expect to find such a relation, there being in men no periodical disturbance comparable to those of menstruation. In sporadic cretinism, which is really only myxœdema occurring in childhood, the affection of the two sexes appears to be about equal, boys and girls alike in those cases being affected by developmental error. It is only after the full development of the sexual organs that the disproportionate implication of women becomes evident. So far as I know the occurrence of sexual development in sporadic cretinism, for the most part very delayed, does not affect the further course of the disease in either sex. The boy and the girl suffering alike from their myxœdema carry it on with them equally when they respectively become man and woman.

In relation to the points which have just come under discussion I may draw attention to an exceedingly interesting paper read by Dr. George R. Murray at Edinburgh in July last on the Diagnosis of Early Thyroidal Fibrosis. The object of this paper is to draw more attention to a class of cases of early disease with partial disablement of the thyroid gland, which are more common than is generally supposed. Dr. Murray points out that the symptoms in these cases are not yet sufficiently well recognised and he regards the symptoms to be the result of a certain amount of atrophy of the glandular tissue of the thyroid with fibrosis, but he does not think it desirable to discuss the question as to the possibility of fibrosis being primary and leading to atrophy of the secreting epithelium as a secondary result or to fibrosis as a secondary condition following atrophy.

Treatment.—Under the head of treatment it must first be observed that until the introduction by Dr. Murray of the practice of making hypodermic injection of a glycerine extract of the thyroid gland no remedies could be spoken of as effective. Arsenic and iron were suggested by the very obvious presence of anæmia, and each in its way often produced some improvement in the general health of the patients. The hypophosphites were used where the nervous weakness was particularly evident and jaborandi or the salts of pilocarpin were used in order to favour the occurrence of perspiration. In addition to the use of drugs the introduction of portions of thyroid gland into the tissues of the body has been used by several observers. Some found a resting place for the gland in the peritoneal cavity, others in the tissues beneath the skin. I may say that I myself have made use of the latter method in several cases, choosing a spot over the upper part of the pectoralis major muscle where the portion of the thyroid gland could be deeply embedded in subcutaneous tissue. In all cases some improvement rapidly followed the operation; the skin began to be moist, the patient's face to fine down, and the hair recovered somewhat of its healthy character, but in no very long time it could be ascertained by the touch that the embedded gland was diminishing in size and at length it had disappeared. With its disappearance passed away also all the signs of improvement. I suppose that it is just possible that by regular repetition of the process some thing like cure might have been effected, but I do not know that anyone has performed the operation more than once or twice, the difficulties of such a proceeding being very obvious. It must be stated that the embedded glandular structure was taken from a goitre just removed by operation.

As I have already observed, after Dr. Murray had made his important discovery Dr. Hector Mackenzie found that the internal administration of the gland or its preparations brought about as marked an improvement and progress to cure as had been effected by the hypodermic injections, and I suppose that the internal administration of the thyroid gland in one way or another is the method of treatment now usually adopted. It appears to me that the administration of the thyroid gland itself when it can be carefully and

Digitized by Google



regularly maintained is the most appropriate form of treatment. The gland may be finely minced and administered raw with sugar or salt or may be lightly cooked. The size of the gland, mainly obtained from the sheep, varies a good deal and such variation is to some extent a justification of the administration of an extract obtained from a number of glands so as to get something like an average. In one case still under my occasional notice an affectionate husband has been at the trouble to procure regularly thyroid glands from sheep and to prepare them in a raw state for administration to his wife. The original quantity administered was one gland a week, but as the patient has improved the frequency of administration has been diminished, but it still goes on as it has gone on for some years and at the present moment the woman presents no signs whatever of the disease. It is possible to give the thyroid gland too frequently. When the knowledge of its efficacy as administered internally first became known I gave to a patient, who was so ill as hardly to present any chance of maintaining life, one gland a day for four days in succession. At the end of that time she suffered from violent headache, vomiting, and pains in the limbs with a rise of temperature amounting to 6° F. With such a lesson the gland was administered at longer intervals—namely, of from a week to ten days—with ultimately the greatest benefit. But to procure fresh and healthy glands and to prepare them in the proper way involves a great deal of trouble and their use may be replaced by the administration of Dr. Murray's glycerine extract in doses varying from ten to thirty drops a day, or every second or third day, according to the effects produced and to the patient's power of bearing the influence of what we may call now the drug. Still more convenient and not ineffective are the preparations in the form of tabloids now in common use. Some of these contain the dried and crushed gland, others extracts of it, such as the excellent powders devised by Mr. Edmund White, B.Sc., the pharmaceutist of St. Thomas's Hospital. On the whole I prefer the extracts of the whole gland to any kind of principle derived from it by chemical processes. Perhaps the next best form is the dried and powdered gland of the Pharmacopœia.

A good deal of extremely interesting work relating to preparation has been done by various observers, and I would draw your attention to "Observations on the Chemistry and Action of the Thyroid Gland," by Dr. Hutchison, Demonstrator in Physiology at the London Hospital Medical College. According to Dr. Hutchison and others colloid matter prepared in various ways from thyroid gland is found to contain a definite quantity of iodine, which appears to be present in the form of what has been called "iodothyrin" (Bergmann). We may note in passing that according to Dr. Hutchison parathyroids when administered in myxœdema have no effect upon the disease, although in operations on dogs no myxœdema occurs if the parathyroids are not removed as well as the thyroid.

The urine.—For the most part the urine in myxœdema contains no albumin, certainly not as a rule until the disease has lasted a very long time, often not at all from beginning to end. Where albumin, however, is present regularly in the urine, together with casts and degenerated epithelium, we may regard it as an indication that the kidney has undergone an internal change comparable to that observed in the eyelids, where the glandular tissue is injured by the encroachments of swollen connective tissue. In post-mortem examination the kidneys are found somewhat enlarged and exceedingly tough, reminding one in their consistence very much of the kidney of advanced heart disease. This change in consistence is associated with excessive thickenings of the connective tissue around Malpighian bodies and between the tubes—changes at first sight very like those of the contracting granular kidney. In the case of the young man who died with cerebral hæmorrhage some increase of interstitial tissue in the kidneys with great degeneration of epithelium, especially that of the convoluted tubes, was noted. Further, as regards the urine three things have long been observed as occurring in the treatment of myxœdema by the administration of thyroid. First, the urine below the average quantity before the administration was very largely increased in the first days of treatment. Secondly, the quantity of urea present in the urine before treatment, long known to be very deficient, amounting often to less than half of the proper excretion in that fluid, was found under the treatment to be very much increased in quantity, to a point even above the average. Thirdly, the temperature of the body was found to rise with more or less rapidity from the subnormal range present in the disease to either the normal height or beyond it. After selecting a well-marked case of myxœdema I obtained the valuable assistance of Mr. White. The constituents of the patient's daily diet and of the urine were regularly submitted to chemical examination a week before treatment. At the end of the week the administration of the thyroid in the form of the glycerine extract of the sheep's gland was begun. It was found then that while the weight of the body diminished rapidly during the first week of treatment the daily volume of urine passed rose from 928 cubic centimetres to 1127, being an increase of 190 grains; that the total solids increased from 26·16 grammes to 36·49; the organic matter from 18·79 grammes to 27·65 grammes; the urea from 14·21 to 22·36 and the total nitrogen from 7·39 to 12·08 grammes, there being also a distinct increase in the quantity of phosphoric acid and chlorine. It was clear, therefore, that the thyroid extract had: (1) a distinct diuretic action; (2) that the elimination of nitrogen was largely increased; and (3) that the increased elimination of nitrogen was almost entirely in the form of urea. These results appear to indicate that during the process of the melting of the myxœdematous deposit there occurs some important metabolism of a nitrogen-containing substance. These observations were brought before the Clinical Society of London some years ago.

In conclusion, I may be permitted to say that myxœdema presents for us great interest in the matter of its primary diagnosis; that it presents for our consideration many problems besides those connected with its own etiology and course and its relations with other diseases in which affection of the thyroid is present; and that in its pathology there are also many points to be investigated and explained. I have dealt only lightly with its pathology for the reason which I have already given—namely, that the setting forth of this before you will presently be found entrusted to more skilful hands.

A Clinical Lecture,

BEING

SOME DETAILS IN POSTERIOR GASTRO-ENTEROSTOMY, WITH TWO SUCCESSFUL CASES.

By ARTHUR E. BARKER, F.R.C.S. ENG.,

PROFESSOR OF THE PRINCIPLES AND PRACTICE OF SURGERY AND PROFESSOR OF CLINICAL SURGERY AT UNIVERSITY COLLEGE AND SURGEON TO UNIVERSITY COLLEGE HOSPITAL.

GENTLEMEN,—The operation of *posterior* gastro-enterostomy being yet on its trial it appears desirable that all details which may facilitate its rapid and accurate completion should be carefully studied. If the procedure is ever to be of real use it must be shown to involve but little risk to the patient. Only in this way will it come to be employed either for cancerous or cicatricial stenosis of the pylorus at a stage when it is most likely to be of real service. Hitherto it has been reserved almost exclusively for desperate cases and consequently the mortality has been high. This latter point, again, has deterred many from employing the measure even in those cases where it would have given great relief from suffering and if successful have prolonged life. This is, of course, equally true of the anterior method as well as of the posterior. But I venture to think that we have been inclined to assume too easily that because the mortality from the first-invented anterior method has been high that therefore the *posterior* method, which appears at first sight to be more difficult, would be higher. This does not necessarily follow. As a balance to the assumed difficulty of the posterior operation we have in it the absence of several of the well-known risks of the anterior method, and notably of the kinking of the bowel and the tendency if a button is used that the latter will fall into the stomach. Statistics do not help us much in estimating the relative risks of the two procedures, inasmuch as the figures available in regard to the older method include many cases done while the procedure of gastro-enterostomy was in its infancy and was consequently imperfect and more dangerous. The figures relating to the much newer *posterior* method, on the other hand, are taken from a period in which surgical technique has undergone immense improvement and the mortality of all operations has greatly fallen. But this much may be said, that some operators of large experience who in the past have done many anterior gastro-enterostomies are now giving it up in favour of the posterior method. And one, Professor Carle of Turin, writing at the beginning of this year, claims to have done his last 23 posterior gastro-enterostomies consecutively without a death, and puts his gross mortality at 3·8 per cent. for non-malignant cases. It may be objected to this series that it only contains non-malignant and consequently less severe cases. But, on the other hand, it probably gives a better idea of the intrinsic risks of gastro-enterostomy *per se* than one including malignant cases, many of them probably operated on in the last stages of an exhausting disease. But if anything like Professor Carle's success comes to be the rule, and a mortality of from 3 to 5 per cent. is all that has to be feared, one of the strongest reasons against timely operations for gastric disease will no longer exist.

But for such results great attention will be necessary to every detail, in addition to the careful selection of cases. Foremost among these will come the preparation of the patient by careful washing out of the stomach beforehand. This should never be omitted and should be carried out for some days anterior to the operation. Next to this comes the cleansing of the skin of the abdomen. For this purpose I am inclined to depend, in addition to plentiful soap and water, chiefly upon washings with methylated spirit and carbolic acid, 1 in 20, alternately if possible, for at least forty-eight hours before the operation. Then the retention of warmth in the patient comes next. My own method to this end, employed for years past, is to envelop the patient from head to foot in hot wool secured by bandages, both now always sterilised beforehand by steam. In cold weather hot bottles are placed round the patient on the operating table.

But it is to some of the details more immediately connected with the actual operation that I think attention deserves specially to be called. In the first place there appears to be a growing conviction among those who have the largest experience of plastic surgery in the abdomen that the less germicides are applied to the peritoneum the better for the result. Every irritant applied to the peritoneum is a most powerful depressant. Fully impressed with this view I have for a long time past carefully abstained from the use of any antiseptic within the abdomen in these cases and have been content to see that everything coming in any way in contact with the viscera is carefully sterilised by heat. Plain, sterile, warm dry gauze has taken the place of carbolised sponges and so on. If fluid for washing is required, which is rare, it is simply plain boiled water. Then special care is required by all and every means to save time and the manipulation of the abdominal contents. Much may be done in this direction by preparation of all detail before the abdomen is opened and much may subsequently be done as well. But in the first place it is very desirable to make the initial incision as small as possible until the exploration of the condition of the stomach has been completed. It is hardly ever necessary to make in the first instance an opening in the muscular wall of more than 2 in. The skin wound may be double that length. But with one or two fingers in the abdomen the stomach can in most cases be explored adequately, and during this exploration there is a minimum of exposure of the viscera and very little chance of prolapse of bowel. Of course, if this opening is not sufficiently large it can be increased with scissors. As a matter of fact, in the class of patients who require such operations emaciation is usually marked, and both exploration and the subsequent operation can be carried out through a relatively small abdominal incision.

And now I desire to call attention to two small modifications of the usual operation which I know will save much time and a good deal of unnecessary manipulation of the field of operation. And first let me say that, although by no means an enthusiastic believer in the wholesale use of Murphy's button, I think that in this particular case of *posterior* gastro-enterostomy it has great advantages. Its use certainly makes an operation which without it is very difficult and tedious comparatively easy and short. And, besides, some of the objections to its use in the anterior operation have less weight in the posterior. Two drawbacks to the use of the button in the *anterior* operation occur at once to any surgeon who has done many of these operations. One is the probability that the button will fall back into the stomach rather than pass into the bowel. This has been known to occur in several cases. It can be explained both by the weight of the metal body tending to drag it back from its position in the anterior wall of the stomach into the cavity of the viscus and from the narrowing of the jejunum due to the dragging of the colon preventing the button from passing into the gut. But when the button is placed in the posterior wall of the stomach behind the colon and in the jejunum behind the latter, where it does not kink, the contractions of the stomach and gravity both tend to carry it into the gut, which is at its greatest size and in no way displaced.

But again I have to note two small details in the method of applying the button in the posterior operation which I observed in my last two gastro-enterostomies, which I think materially shorten the procedure and further minimise the chance of the button falling into the stomach. The first is Professor Carle's method of closing each viscus round the central tube of the button, which differs materially from that recommended by Dr. Murphy. The incision in each viscus was made only just large enough to get the button into each. Then, instead of the usual purse-string suture round the edges of the opening to close it on the central tube Professor Carle simply puts a stitch at each end of the slit by Lembert's method and so reduces it. This saves much time, as he says, and as I know from my own cases, and is equally effectual. It also saves much handling and dragging of the parts.

The next point to which I wish to draw attention I have not seen noticed elsewhere. It is a departure from von Hacker's procedure in his operation. He recommends that when the stomach has been reached through a slit made in the transverse meso-colon it should be secured there by stitches before being made to anastomose with the jejunum.

Digitized by Google

Now I believe that this stitching, although I have done it in my own operations, may be dispensed with altogether where the button is used. That this will save much time is obvious. In my last case the operation had lasted seventeen minutes before this stage had been completed, the whole procedure lasting thirty-six minutes. From what I have seen in the last two cases I have operated on I believe that all that is necessary is to make a small hole in the meso-colon and draw the posterior wall of the stomach through it to a sufficient extent to give room for the insertion of the metal button. When the latter has been placed in position it will prevent the stomach from slipping back through the slit in the meso-colon and there will therefore be no reason for stitching the latter to the stomach. There might be some fear perhaps that the funnel of the stomach-wall thus made might be strangled by the edges of the hole in the meso-colon did we not know that under similar conditions where the stomach is drawn out through small apertures in the most recent operations for gastrostomy no strangulation takes place. In my first posterior gastro-enterostomy, though the stomach-wall was tightly grasped by the hole behind the button, no evil result followed and the button was passed on the fourteenth day, the patient making a perfect recovery. In my last case of the posterior operation done with the same button I stitched the stomach to the meso-colon. But though the patient made an uneventful recovery and the button was passed on the twelfth day I could see that I had lost at least ten minutes in putting in stitches in a very inaccessible part which might have been avoided. Everything which gets rid of the necessity of stitching within the abdomen appears to me to deserve a very careful consideration as a means of saving time and the irritation of manipulation.

In conclusion, I may say that I was struck with the very small amount of general disturbance produced by the posterior operations as contrasted with a much larger number of anterior gastro-enterostomies which I have done. The operation in every way left a very favourable impression on my mind. And if further experience shows that it can be done in a still shorter time and with equally rapid and satisfactory recovery we may hope that many sufferers may be relieved at a much earlier stage of their ailments than has hitherto been the case. The cases are briefly as follows.

CASE 1.—A patient, aged fifty years, was sent to me by Mr. Smith of Tavistock with a history that he had just arrived from Italy. He had been a healthy man until some six or eight months before, when he began to suffer from dyspeptic symptoms accompanied by pain and great dilatation of the stomach. Some seven years before he had had somewhat similar symptoms but had recovered and become very stout, weighing usually about 15 st. The last attack was followed by rapid emaciation, so that when I saw him he only weighed 10 st. 8 lb. He had been treated by careful dieting and washing out of the stomach daily and under this treatment the dilatation of the organ disappeared but with increasing weakness. No tumour could be made out. In the uncertainty as to diagnosis an exploratory operation was done on Aug. 27th, 1898, in which I discovered a hard, thickened pylorus, possibly cicatricial, but presumably carcinomatous. I turned up the colon, made an opening in the transverse meso-colon, and united the stomach through this to the first part of the jejunum about 18 in. from its origin. Murphy's button was used, as above described. The patient bore the operation, which lasted fifty minutes, well. He was troubled for the first two or three days by regurgitation of bile from the mouth. After this he had no trouble and soon began to put on flesh at the rate of 3 lb. every two days. He left the nursing home looking well and very cheerful, having passed the button on the fourteenth day.

CASE 2.—A man, aged forty-eight years, was admitted into University College Hospital in the last week of September, 1898. He was much emaciated and suffered severely from pain and dilatation of the stomach and there was a tumour to be felt in the pyloric region. Here I did the operation of posterior gastro-enterostomy precisely as in the previous case but more rapidly, finishing it completely in thirty-six minutes. The stenosis was undoubtedly cancerous. The patient was none the worse for the operation, was fed from the first, and soon began to put on flesh rapidly. He had no bad symptom of any kind and returned home on Oct. 26th, 1898, without any of his old pain and eating ordinary food. The button was passed on the twelfth day.

A FURTHER CONTRIBUTION TO THE SURGERY OF STONE IN THE BLADDER,

BASED ON A RECENT SERIES OF CASES IN HOSPITAL AND PRIVATE PRACTICE.

BY REGINALD HARRISON, F.R.C.S. ENG.,
SURGEON TO ST. PETER'S HOSPITAL.

FROM time to time I have passed under notice [1] and compared with my own experience various processes which have in recent years been employed in the treatment of stone in the bladder and have endeavoured to illustrate their applicability to individual cases in practice. The record of additional cases which forms part of this paper will enable me to offer some further remarks on various points still open to consideration. The cases here referred to have all been operated upon by me either in hospital or private practice during the interval of 1890–97 and include every instance thus dealt with during this period. It will be convenient to divide my subject-matter into three parts: (1) a tabulated record of all my operations during the period referred to, with special reference to litholapaxy as the procedure now generally adopted; (2) observations relative to the prevention and treatment of recurring stone; and (3) some remarks on certain operations for stone in the bladder which may be regarded as supplementary to litholapaxy.

I.—A TABULATED RECORD OF OPERATIONS DURING THE PERIOD 1890–97, WITH SPECIAL REFERENCE TO LITHOLAPAXY AS THE PROCEDURE NOW GENERALLY ADOPTED.

To proceed with my first division it will be seen on reference to the table of cases that it comprises 101 litholapaxies, 3 perineal lithotrities by my method, 2 suprapubic lithotomies, and 4 median lithotomies, making a total of 110 persons operated upon.

Litholapaxy.—Since 1878, when I was in Boston and spent some time with Bigelow watching his earlier operations by this process, which he was then developing, I have continued to practise it, using with but slight modifications the appliances which I showed for the first time in England at the annual meeting of the British Medical Association in 1878 [2] on my return from the United States. No more striking testimony to the completeness of Bigelow's work could be found than the fact that the instruments of his day, after a lapse of over twenty years, have undergone no important change. It is rare to find an invention so perfect in its initiation as this in all its details. On reference to the table of cases it will be seen that 6 of the 101 litholapaxies terminated fatally. 1. A man, aged sixty-five years (No. 6), who was operated upon successfully on the first occasion, died on the third day after the repeated operation which was performed thirteen months subsequently. The kidneys were extensively involved in suppurative nephritis. The stone was a phosphatic one weighing close upon 2 oz. The repetition of the operation had clearly been delayed too long. 2. A man, aged sixty years (No. 13), died on the twenty-eighth day after operation from chronic suppurative nephritis and syncope. 3. A man, aged seventy-two years (No. 32), died on the sixth day after operation from pelvic cellulitis probably due to suppuration within a vesical sac or pouch. 4. A man, aged fifty-four years (No. 70), who was operated upon successfully on the first occasion, died after a similar operation repeated fifteen months subsequently from suppurative nephritis caused by a chronic urethral stricture which had gradually contracted. Had on the second occasion a perineal lithotrity with division of the stricture and drainage of the bladder and ureters been practised he would have had a better chance of recovery. The patient derived so much relief from the first operation that he wished it repeated on precisely the same lines. 5. A man, aged sixty-two years (No. 88), died on

the tenth day after operation from extensive suppurative nephritis consequent on a urethral stricture of some years' standing. He was much exhausted from many weeks' travelling under painful circumstances. 6. The remaining fatal case was that of a man, aged seventy-six years (No. 92). He died on the twenty-ninth day after what promised to be a very successful operation. A large urate stone was crushed and evacuated, the dried fragments of which weighed 975 gr. The prostate was much enlarged. The calculus had previously caused him great pain and the operation afforded complete relief from this. He died from senile decay. Of the 101 different persons included in the table and who were submitted to litholapaxy 23 were known to have one or more recurrences for which I treated them on subsequent occasions. One man (No. 17), I heard, had a second stone successfully removed by another surgeon by a suprapubic cystotomy about twelve months after my operation. In these 23 persons who had recurrence of stone after crushing I repeated litholapaxy once in 13 of them, twice in 2, thrice in 1, four times in 1, five times in 1, six times in 1, nine times in 2, and ten times in 2, making a total of 174 litholapaxies in 101 individuals with six deaths as previously detailed. In several of the repeated operations the proceeding resolved itself into occasionally removing from the bladder calculous concretions with the aid of the lithotrite and aspirator, much on the same principle as the dentist removes tartar which has collected about the irregularities of the teeth. These occurred for the most part in elderly men with atonic bladders who were more or less dependent on their catheters and possessed but little power of voluntary expulsion. To submit these cases to a cutting operation for the purpose of removing the concretions and draining the bladder could not be recommended, as during the intervals, sometimes extending over many months, they enjoyed fair, and even active, health. For instance, in case No. 1 the patient, whom I first operated upon early in 1890 and upon whom I have repeated the operation nine times, is alive and well, and though not in robust health leads as comfortable a life as most people do at seventy-one years of age who are dependent upon the catheter. No. 3, operated on in 1890, followed by two recurrences at about three months' interval each, has had no recurrence since 1891, and is now again leading an active professional life. No. 4 had the operation repeated six times, but has had no recurrence since 1893. He is now eighty-seven years of age and is in good health. No. 44 has had nine recurrences. He is in excellent health, though he has recently had another operation after a previous two years' interval. I have since divided both his vasa and I think it likely that he will be no further troubled either with stone or prostatic symptoms. These cases were all unfitted for any other procedure. In none of them have the patients hitherto shown any signs of kidney complication.

As in records by other surgeons which have been recently published, the mortality connected with all these proceedings has been reduced to so small a percentage as to assimilate them in this respect to those which we are accustomed to speak of as minor or non-fatal operations. The period of convalescence has also been considerably lessened. In both of these important respects there has been generally a remarkable diminution during the last twenty-five years of the present century.

The stones noted in the table both as to composition and weight include all the commoner varieties of calculi and one cystin (No. 96). The collected and dry fragments of the 101 primary litholapaxies were found to weigh 13,413 gr., or an average weight of over 2 dr. removed from each patient. The largest calculus in this litholapaxy series was a urate (No. 64) which weighed 1200 gr. In the 73 operations undertaken for recurring calculi the fragments removed varied from about 20 gr. in weight to over 2 oz. These calculi were for the most part phosphatic. The youngest patient operated upon (No. 73) was a boy four years of age. A urate calculus weighing about 15 gr. which had caused several acute attacks of retention of urine, was pushed back into the bladder and then crushed and evacuated. He was well and about on the following day. In the same way a cystin calculus was removed from a boy five years of age (No. 96).

A urethral stricture complicated several of the cases of litholapaxy (Nos. 12, 23, 26, 54, 55, 70, 84, and 88). Urethral stricture, as several of these cases show, offers no obstacle in the way of litholapaxy provided the kidneys are fairly sound and have not commenced to suppurate. When the latter has taken place litholapaxy can only be undertaken with a considerable degree of risk. This complication proved fatal in cases No. 70 and No. 88. Where stricture is of that degree of tightness or of previous duration as to render suppurative nephritis imminent or actual, perineal lithotrity, with division of the stricture and subsequent drainage, is far safer. Case No. 104 of the series is another illustration of this. This patient had been treated for stricture for over a year before I sounded him and found a large stone in addition. Litholapaxy would probably have been fatal in not providing drainage for the suppurating bladder, ureters, and kidneys. Perineal lithotrity was selected and since the operation, over four years ago, he has enjoyed excellent health, and has had no recurrence either of stone or of stricture. In 2 of the cases (No. 33 and No. 100) the stone was embedded within the area of the prostatic urethra. In one instance it was seen with the cystoscope. With a sound aided by my finger in the rectum in both cases the stone was freed, pushed back into the bladder, and crushed.

In looking over the table of cases which accompanies this paper it will not be difficult to recognise that prostatic hypertrophy and the conditions associated with it most frequently co-exist with stone recurrence. I shall therefore pass on to the second part of my paper and proceed to offer some observations relative to the prevention and treatment of vesical stone when met with under these circumstances.

II.—Observations Relative to the Prevention and Treatment of Stone Recurring after Operation.

It is only in connexion with the surgical treatment of stone in the bladder when complicated with prostatic enlargement and the vesical conditions associated with this that it becomes necessary to offer any special remarks in reference to stone recurrences after operation. Litholapaxy or crushing when practised on the child or the young adult under normal structural conditions is so rarely followed by the re-formation of stone as hardly to require notice. It happened only once in this series under the latter circumstances (No. 17) and this was probably due not directly to bladder causes, but to a fresh descent from the kidney, as also occurred in a second instance (No. 33). The remaining recurrences and a large proportion of the entire number of litholapaxies were associated with this particular form of urinary obstruction. There is nothing very remarkable in this when we remember that, excluding three or four young persons about or below puberty, the average age of the patients was over sixty-two years. Nor is it difficult to understand why this should be. The enlarged prostate not only often renders the act of complete micturition mechanically difficult and impossible, but it furnishes favourable local conditions for the growth of stones which, having descended from the kidney, are thus detained there. Under such circumstances the male bladder may not inaptly be regarded as a bedding-out ground for renal calculi. Many instances in this series served to illustrate this and to show how gravel and calculi which were formerly expelled naturally ceased to be so as soon as the prostatic age had been reached. And what applies to kidney calculi and concreted crystals is equally true of other foreign bodies which a chronically-inflamed bladder is apt to contain. That an incomplete removal of the débris after a crushing operation may be responsible for some recurrences there can be no doubt, but not, I believe, to the same extent as some are disposed to consider. A red urate or a black oxalate stone is sometimes supplanted by a pure white phosphate. More than one recurring calculus which I have removed had a fixed origin on the rough cicatrix of a previous suprapubic cystotomy; two were formed on centres furnished by the remains of silk sutures employed in the latter operations, and others undoubtedly have had their origin on nuclei provided by shreds and sloughs from an inflamed bladder. Further, the sacs and pouches of bladders distorted in this way by prostatic obstruction furnish hiding places for débris which are almost inaccessible. In view of such obstacles and to prevent recurrence taking place much importance must be attached to the thorough clearance of the bladder in the first instance, to the subsequent management of the case after it has left the hands of the operator, and to such measures as have for their object bringing about shrinking or atrophy of the enlarged gland.

The lithotrites employed should be capable of rapidly and completely breaking up the stone without pounding it too much into such masses as a pestle and mortar produces. The jaws of the lithotrite whilst protected should be able to

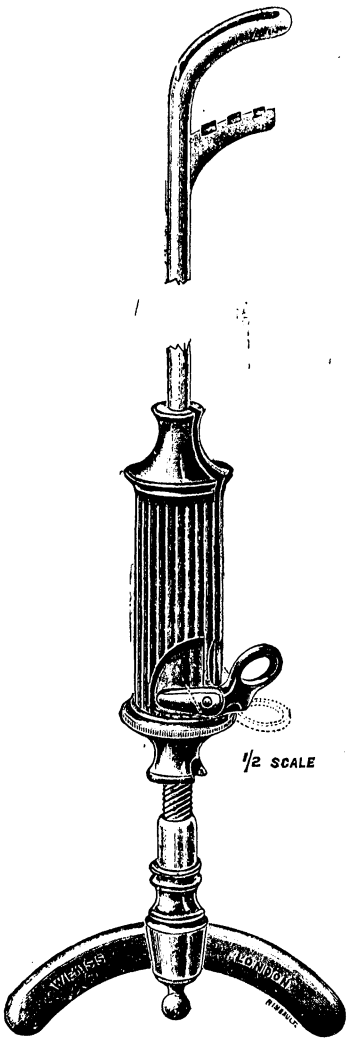
REMARKS.



Case 6: Operation repeated 13 months afterwards; death. Case 9: Prostate subsided after removal of stone. Case 12: Urethral stricture dilated. Case 13: Advanced kidney disease. Case 14: Pouch seen with cystoscope. Case 16: Diabetic. Case 17: Suprapubic cystotomy a year subsequently; recovery. Case 18: Double vasectomy subsequently for enlarged prostate; good result. Case 23: Urethral stricture treated by dilatation. Case 26: Urethral stricture. Case 32: A suppurating saccule and pelvic cellulitis caused death. Case 33: Stone saculated in prostate pushed back and crushed; shrinkage of prostate; recurrence due to fresh descent from kidney. Case 48: Paralysed. Case 54: Tight stricture: (1) internal urethrotomy and (2) litholapaxy. Case 55: Internal urethrotomy for stricture 13 months previously; nucleus of stone a bougie of ol. theobrom. Case 56: Single vasectomy for enlarged prostate on recurrence. Case 60: Double vasectomy for enlarged prostate. Case 66: Very small and contracted bladder with a pouch; double vasectomy. Case 69: Pelvis much distorted by old spinal caries. Case 70: Chronic stricture of urethra; litholapaxy repeated 15 months after; death; suppurative nephritis. Case 71: Double vasectomy for large prostate. Case 73: Impacted stone causing retention; pushed back and crushed. Case 74: Suffered much from chronic bronchitic asthma. Case 78: Complicated with large hydrocele. Case 79: Mucous membrane encrusted with phosphates. Case 81: Incontinence of urine for 3 years previously and constantly wearing a urinal; power of bladder completely restored after operation. Case 84: Chronic urethral stricture. Case 88: Complicated with old stricture and suppurative nephritis. Case 92: Much relieved by operation; death from senile decay; urine specific gravity 1008. Case 94: Double vasectomy for enlarged prostate. Case 100: Prostatic stone pushed into bladder and crushed; shrinkage of prostate. Case 101: Stone seen with cystoscope in orifice of left ureter. Case 102: Lithotrity attempted, but perineal lithotrity substituted. Case 104: Chronic urethral stricture; pyelitis; division of stricture. Case 106: A villous growth was also suspected, but not discovered. Case 110: A stricture necessitated division and drainage.

Note.—All the cases were those of male patients except No. 79, which occurred in a female.

out up stones such as the phosphates, which though soft and friable are apt when mixed with the mucus from the bladder to run into tough pultaceous pieces which may readily be left behind and form nuclei for further concretions. Hence the powerful fenestrated lithotrites are, as a rule, to be preferred. For use with large stones the lithotrite last made for me (Fig. 1) by Messrs. Weiss and Son has proved a most

FIG. 1.

The lithotrite.

FIG. 2.

The aspirating catheter and stylet.

admirable pattern. It will be seen that to save the hand a cross-bar has been fitted to it instead of a wheel and a short lever worked by the thumb, in place of the old button, by which the sliding movement is converted into the screw when the stone is seized. It must, however, not be forgotten that the former adaptation greatly increases the power which can be brought to bear upon the instrument. A cautious operator will consequently be chary how he utilises his maximum force. Nor must the aspirators and catheters used for withdrawing the broken fragments from the bladder be less efficient. In this series of cases I have continued to use Mr. Morgan's aspirator. My colleague Mr. Freyer has recently described one which is extremely simple and is readily charged with water. The opening or eye in the evacuating catheter should be large and bevelled (Fig. 2) and a probe stylet should be at hand in case of impaction.

In cases complicated with prostatic enlargement and where the patient is, as is often the case, more or less dependent upon the catheter, the bladder should be attended to for some time after the operation. Sufficient importance is not attached to this point. If these cases were carefully looked after for three or four months after the operation, recurrences would be far less frequent. At least once a week the bladder should be washed out with the metal catheter and aspirator, as used in connexion with the operation, in addition to such irrigation and catheterism as the patient can himself employ when necessary. I have also had some large-eyed flexible catheters made to fit these aspirators. The latter are sometimes useful where there are sacs or pouches. The aggregation and growth of calculous matter in the bladder may thus often be prevented. I recently saw a boy, aged four years, who had many of the symptoms of stone. I sounded him under ether but could not find one. I then washed out his bladder with an aspirator catheter as just described and removed quite a quantity of large urate crystals with complete relief to the patient. It was, as Mr. Braine remarked at the time, "a good stone spoilt." Free crystals remaining in the bladder are not an infrequent cause of various irritations and reflexes in young subjects.

The effect of silver nitrate as a local application in cases of chronic cystitis with prostatic enlargement where there is a tendency to produce phosphatic concretion is well known. I remember a case some years ago which bears importantly upon this practice. It was that of an elderly man who when suffering from residual urine broke a gum-elastic catheter whilst passing it and left several inches of it in his bladder. His general condition was such that no immediate steps could be taken to remove it and it was therefore advised that the bladder should be washed out twice a day with a weak solution of silver nitrate. This was done and ten days afterwards the patient allowed me to extract the broken portion entire with a smooth-bladed lithotrite. What struck me on doing so as remarkable was that neither on the piece of catheter nor within the bladder was there any sign of phosphatic concretion. I presume that the action of the nitrate, as with other salts which may be artificially introduced into the bladder, prevented molecular coalescence taking place, as the urine was alkaline and offensive during the ten days the catheter remained in the bladder.

In the third place, my series of cases furnishes examples (Nos. 18, 56, 60, 66, 71, and 94) where vasectomy was employed with the view of bringing about shrinkage of the prostate. It appeared to do good in all these instances, (1) in rendering access to and from the bladder easier both as to micturition and the use of catheters, and (2) in getting rid of that slimy mucus, not unlike birdlime, which clings so tenaciously to the bottom of vessels in which it is allowed to settle. Vasectomy was resorted to under these circumstances in instances where in addition to the recurrence of the stone serious symptoms of prostatic obstruction existed. The stone having been removed in the usual way by the lithotrite and aspirator, one vas was resected in the way described in my Bradshaw lecture[3] and seven days afterwards the remaining one was treated in the same manner, about an inch of each tube being taken away. The small wound usually heals under a collodion dressing in forty-eight hours.

I have never had occasion to resort to castration in connexion with my stone operations, as I think that a trial should first be made of vasectomy before so serious an operation is proceeded with. I have, however, recorded one instance in my Bradshaw lecture (where I have discussed this subject at some length), in which I know excellent results followed castration in a case of recurring stone with urgent and increasing symptoms of prostatic obstruction. In the instances of vasectomy just referred to no recurrence of stone has yet occurred to my knowledge and there has been a general improvement in the symptoms connected with the enlarged gland which co-existed. I think a further experience and a still more extended period of observation will warrant me in concluding that the diminishing number of recurrences in this series was due not entirely to any additional pains taken in the first instance in the removal of the stone, but partly also to the use for some time after of the evacuating catheter and wash-bottle and to the employment of vasectomy on recurrence, in suitable cases, where there was much prostatic enlargement, which practices I have more recently adopted. I will now proceed to the third and concluding portion of my subject.

III.—SOME OPERATIONS WHICH MAY BE REGARDED AS ALTERNATIVES OF LITHOLAPAXY.

In the last nine cases of stone in the bladder arranged in this series (No. 102 to No. 110) it was thought necessary to employ some form of incision to facilitate the removal of the

[3] THE LANCET, Dec. 12th, 1896.

Digitized by Google

calculus, either entire or by first breaking it. The selection of one or other of these proceedings had reference mainly to conditions or complications outside the mere presence of a stone, as in no instance was the latter itself deemed to be beyond the reach of litholapaxy. In every instance recovery was complete and, so far as I know, permanent. The average age of these nine individuals was about forty-six years, whilst in the previous series of litholapaxies the average was about sixty-two years. In 3 of these cases perineal lithotrity on the lines I have elsewhere described was selected; in 2 suprapubic lithotomy or the high operation was practised; whilst in the remaining 4 the boutonnière or median operation was employed as providing for the extraction of the stone and the subsequent drainage of the bladder, the latter being the main consideration. A few words will be devoted to noting the special advantages connected with the several proceedings and their application to some of the cases selected.

Perineal lithotrity.—The chief reason for selecting this mode of dealing with the stone in the three patients (No. 102 to No. 104) may be very briefly stated. It was essentially a mechanical one, having reference in the first instance to an extremely contracted and thickened bladder, where after trial it was found impossible to use the lithotrite with safety in such a limited area; in the second instance to an unusually rigid or fibrous prostate which rendered the introduction of the short curved lithotrite exceptionally difficult; and in the third instance to a very strictured urethra. The patient in the third case had previously undergone an internal urethrotomy and two divulsions by Holt's method by other surgeons and the canal was structurally unfitted for the instruments used in crushing operations. Further, as will be readily understood, suppurative nephritis was impending if not already in existence. The patient made a good recovery. In these three cases, in addition to the special features I have mentioned the stones were large and hard, weighing respectively 430 gr., 1446 gr., and 480 gr. In one of the patients (No. 103) who was submitted to perineal lithotomy in 1893, nine months afterwards he had an attack of cystitis which threatened to become chronic. As this would probably have led to a recurrence I opened and drained the bladder from the perineum for ten days. This speedily cured the cystitis. I hear that the patient continues to have excellent health and has had no return of the stone. In a previous series of cases in two instances I drained the bladder by a median perineal puncture and drainage-tube where some weeks after lithotrity the urine remained purulent and chronic cystitis continued. In both of these the independent drainage, apart from and subsequently to the removal of the stone, acted beneficially and certainly appeared to complete the cure. In neither of these patients did recurrence take place, though before the drainage was employed it looked as if this was most likely to happen.

The chief points in favour of the selection of perineal lithotrity appear to be these: (1) it enables the operator to crush and evacuate large stones in a short space of time; (2) it is attended with a very small risk to life as compared with other operations, such as lateral or suprapubic lithotomy, and is well adapted to old and feeble subjects when for any reason crushing is inadmissible; (3) it permits the operator to wash out the bladder and any pouches connected with it more effectually than by the urethra, as the route is shorter and the evacuating catheters employed are of much larger calibre; (4) the surgeon can usually ascertain, either by exploration with the finger or by the introduction of forceps into the bladder, that the viscus is cleared of all débris; (5) it enables the surgeon to deal with certain forms of prostatic outgrowth and obstruction complicated with atony of the bladder in such a way as to secure not only the removal of stone, but the restoration of the function of micturition; and (6) by the subsequent introduction and temporary retention of a soft rubber drainage-tube states of cystitis due to the retention of urine in pouches and depressions in the bladder wall are either entirely cured or are permanently improved. To lock up unhealthy ammoniacal urine after a lithotrity in a bladder which cannot properly empty itself is to court the formation or recurrence of a phosphatic stone. Hence it is well suited to some cases of recurrent calculus. I have never known the wound to remain unhealed except in those instances where for some reason or other it has been desired to construct a low-level urethra.

Supra-pubic lithotomy.—This was successfully practised in two instances (No. 105 and No. 106). In both, from the pain and the frequency and duration of the hæmorrhage, growth was also suspected but not discovered. The bleeding was so free and was so readily excited that the cystoscope afforded no assistance, and I thought it better to remove the stones in such a way as to enable me to directly explore the interior of the bladder. No cause for the bleeding other than the calculus was discovered. It is seldom that the latter occasions so much hæmorrhage. The stones weighed respectively 308 gr. and 900 gr.

I am not much in favour of this method in removing large calculi from elderly males. In younger persons it is much safer and there is less objection to it. The mortality is considerable, as shown by Guyon, in males over fifty years of age. The cicatrix which is left in the bladder sometimes greatly interferes with complete micturition and in 2 instances a rough scar was shown on exploration as forming a holding-ground for phosphatic concretion. In one of these instances the scar has been excised with advantage.

Median perineal lithotomy with bladder drainage.—In 4 instances (No. 107 to No. 110) this simple operation was practised for the removal of small stones which were incidental to chronically inflamed and suppurating bladders. The bladder was subsequently drained for varying periods on the same principle as is sometimes utilised in the case of chronic abscesses, a satisfactory result being obtained in each instance.

Nitrous oxide gas and ether were the anæsthetics usually employed throughout the whole series of operations and nothing occurred to make me alter the favourable opinion I have expressed as to this method of producing insensibility. In elderly and debilitated persons with weak hearts the stimulating effect of the ether in improving the circulation was often most marked; nor were any casualties noted in connexion either with the instruments used or the parts operated upon. No serious hæmorrhage was encountered where incisions were necessary and after the litholapaxies it was rare to find the urine tinged with blood forty-eight hours after the operation. Any cystitis which was present at the time of operation usually rapidly subsided after the removal of the stone and no trouble with elevations in temperature, rigors, or fever complicated recovery.

As to sounding for stone I would repeat what I have often said. I much prefer that the stone should be removed where this is practicable on the occasion when it is first detected by the sound and the diagnosis is made. This practice predominated in this series, as the more I see of stone in the bladder the more I recognise the utility of this precaution, particularly in the case of elderly males. Where the prostate is large stones grow up like mushrooms in the pouch-like space between the large prostate and the back of the bladder and make, as it were, nests for themselves. Where there are two or three they often become fitted to each other like tessellated tiles, and if this arrangement is accidentally and suddenly disturbed most acute cystitis is apt to follow. Most of us know how much discomfort a displaced piece of tartar will cause in the mouth until it is completely removed. Even when they are delicately and lightly touched with the sound the stones may get out of gear with their bed, and if urine finds its way underneath them to some unaccustomed spot an acute cystitis may be aroused in the interval between the detection of the stone with the sound and its removal by the lithotrite. In one patient (No. 41) this actually happened and made a simple operation a serious one, as I had to crush and remove the stone seven days after sounding in the presence of a most acute inflammation which otherwise, I am sure, would have proved fatal. He had, as I anticipated, a recurrence and I removed a small phosphatic stone eight months afterwards (in March, 1894). He has since enjoyed excellent health and has had no recurrence. The process of sounding, however skilfully performed, is certainly not an agreeable one and is best accomplished under an anæsthetic. Fewer stones would escape detection and consequently be sooner removed if this was a more general practice. The cystoscope has in several instances been of much service in clearing up doubtful points—for example, in determining the presence and position of pouches or sacs and whether urine derived certain changes observable in it from either, and from which, kidney or from sources below these organs. In one case of encysted calculus (No. 100) not only was the stone seen but its removal was facilitated by exact knowledge as to its location. In another case (No. 101) the cystoscope clearly showed the impaction of a stone in the orifice of one of the ureters.

In conclusion, this series of cases may serve to illustrate—

Digitized by Google

(1) conditions under which the surgical treatment of stone in the bladder, in the adult male particularly, have to be undertaken, at all events in this country; and (2) various operations which may be selected for its cure or relief. Of course, the relative proportions of the latter to each other will vary in some degree, and it is only reasonable that this should be expected. I well remember some years ago, when "lithotomy *versus* lithotrity" was a burning question, being present as a junior at a consultation where after the diagnosis of stone in the bladder had been made the operating surgeon in charge asked the opinion of his senior colleague, a man possessed of much common-sense and surgical experience, as to whether crushing the stone or cutting should be practised. "Whichever you can do best," was the prompt but somewhat curt reply. Lithotomy was selected and the patient made an excellent recovery. I doubt if at that time crushing had been resorted to whether the case would have terminated equally well. Where the pathological conditions were so equally balanced I do not think a better answer could have been given.

Lower Berkeley street, W.

GENERAL PARALYSIS OF THE INSANE: AN ATTEMPT TO ASCERTAIN ITS AVERAGE DURATION AT THE PRESENT DAY.

BY JAMES ADAM,

FORMERLY PHYSICIAN SUPERINTENDENT TO THE CRICHTON ROYAL INSTITUTION, TO THE SOUTHERN COUNTIES' ASYLUM, AND TO THE METROPOLITAN DISTRICT ASYLUM, CATERHAM, ETC.

PERHAPS there are no cases which come under treatment in the various institutions for the insane throughout the country which excite more interest or attract greater attention than those of the prevalent disease known as general paralysis. I use the word prevalent because it is found so in and near large centres of population, although in districts more sparsely populated it may be more rarely met with. Often obscure in its earlier manifestations, there usually no longer exists any doubt as to the actual character of the malady as it presents itself in these institutions, for by the time the case reaches them it has developed at least some of its typical and unmistakeable features. So much has been already written by competent writers on the subject of general paralysis that there is little or nothing left to add regarding its general characteristics and it would not accord with the object held in view by the writer of this article were he to attempt to do so. It may therefore suffice for the present purpose to allude to four stages through which the disease commonly passes and to remark in passing that the duration of those various stages differs much in different cases; that the disease occurs more frequently in males than in females; and that when it does occur in the female sex the symptoms, especially the mental symptoms, differ from those in the male sex.

The first stage which calls for notice is the period of onset during which the patient, with his malady more or less unrecognised, is usually resident in his own home, goes about, or attempts to go about, his daily avocations and still remains a free agent, brooking no control, squandering his money recklessly, and being immoral to his heart's content. The importance of a correct diagnosis being made at this stage is evident, so that proper steps may be taken for care and treatment with as little delay as possible. But these steps are too often, almost of necessity, delayed until much and irretrievable mischief is done.

Then follows the second stage, during which, the disease having fully developed itself, removal to an asylum becomes imperative, and it is usually in this stage that the patient is first seen in such an institution and for the first time becomes subject to carefully and accurately recorded statistics. There is, I think, little doubt that much may be done by treatment during this second stage to favour arrest or possible cure. The value of such arrest or cure if brought about goes without saying, for not a few of those affected by general paralysis are persons of property, and a successful and just disposition of property may be accomplished at such a period.

In favourable cases a third stage sooner or later sets in—a stage of arrest of the disease, during which the patient becomes quiescent and docile and gains flesh. He also regains much of his lost mental power and coherence and self-control return. In some cases he even wholly recovers, there being well-authenticated instances, as recorded below, not only of recovery from well-marked general paralysis but of successful resumption of business, and this even in the busy heart of the metropolis itself.

The fourth stage needs little comment. Utter helplessness is usually ushered in by epileptoid or apoplectiform seizures, and as a rule such seizures are continued or are frequently repeated until exhaustion or coma mercifully closes the scene.

Having thus described the stages through which this strange malady usually passes I will now endeavour to ascertain as nearly as possible the average length of time occupied in passing through them. It will, I think, be found practically that duration is governed by that stage which I have described as the third or arrest stage, for without this the average duration would be infinitely shorter than it even now is. General paralysis of the insane would, in fact, nearly always be a rapidly fatal disease if it ran its course without interruption. A question is not infrequently addressed to the medical practitioner by the guardians or relatives of general paralytics as to the probable duration of the disease after its existence has been ascertained. The question is usually answered by the aid of the general belief that on an average general paralysis of the insane runs its course and terminates in death within two years. My experience for several years has led me to doubt the accuracy of this assumed average, for I have seen so many cases of prolonged arrest, and more than one of recovery, as to suggest the possibility of a general modification of the disease having taken place, rendering it more amenable to treatment. On the other hand, this prolongation may be accounted for by the fact that the experience of later years has been among the more educated classes, and education generally exercises a modifying influence in all the varieties of mental disorder. Be that as it may, I resolved to make the attempt to verify or to rectify if necessary the old-standing estimate of duration and as a first step addressed questions on the subject to the superintendents of all institutions for the care of the insane in England. I was favoured by numerous replies, for which I beg here to express my thanks, and although they are not quite complete the figures so obtained are valuable and enable an approximate estimate at least to be given, which appears to be not far removed from what would prove to be the complete facts of the case. In framing these figures difficulties, of course, presented themselves, not the least of which were the vagueness attending the inception of the disease and the incorrectness or unreliability of the data received with the patients at the various institutions at the time of admission. Moreover, the early symptoms of general paralysis are not always easily recognisable. There are also the wandering cases, which may or may not be recognised or taken notice of at all until a late stage of the disease. The returns obtained were from 26 county asylums, 16 private asylums, 6 lunatic hospitals, 2 military and naval hospitals, and 4 borough asylums. The returns extended over the past ten years, which accounts for the smallness of the return from the borough asylums, some of which have only recently been called into existence. The following figures give the results arrived at:—

Table shoning approximately the Average Duration of General Paralysis (in Male Patients only) in Institutions for the Insane in England, with the Age at Death.

Institutions.	Average duration of disease.		Average age at death.	
	Years.	Months.	Years.	Months.
County asylums	1	10	42	6
Private asylums	2	6	46	0
Lunatic hospitals	1	7	44	0
Military and naval hospitals ...	1	11	37	5
City and borough asylums	1	8	46	6

Thus the correctness of the stated old-standing average is practically verified by the present figures, taken as a whole, although it would appear that the educated and well-to-do

Digitized by Google

classes have a longer period of existence meted out to them after the onset of the disease than have the poorer classes. The explanation of this may be the earlier recognition of the disease in the wealthier classes and the earlier resort to care and treatment.

Annexed are notes illustrative of three typical cases, with recovery in two.

CASE 1. *Undoubted general paralysis with typical and marked mental as well as physical symptoms of the disease.*—The following characteristic letter was written two or three months after onset whilst under care: "I am going to astonish the whole world this week; the papers will be full of it. I am going to reform the world—England to be made a paradise. Work for all the unemployed; no more taxes, workhouses or prisons required. All diseases will be banished; there will be simply a few paying hospitals. No one to be married before they are twenty-four years of age, women twenty-one years. The first thing to do is to get together all the vagabonds, thieves, drunkards, and wife-beaters, and I shall have them punished with a cat-and-nine-tails. The sea to be brought all over England, also electric light, good roads to be made, plants, trees, and wild flowers on the banks. Electric tramcars. I shall have plenty of money to do what I like with. Your dad will 'be a bishop' and my private chaplain. I have learnt to sing and play anything on the piano; you will hardly know me, I am so improved. Nice church and cathedral will be built. I am going all over the world and you shall come to some of the best places with me. Address to me, Grand Hotel, Charing Cross." At the end of six months, arrest having been in progress for some time, a consultation among leading psychologists and neurologists was held in London, with the result that no trace of the mental disease was discovered. A three months' probation followed, at the end of which time the patient was discharged recovered.

CASE 2.—In this case equally typical symptoms presented themselves, but an enumeration of them would prove too lengthy. The patient believed he was making £190,000 per diem, &c.; six months later an inquisition in lunacy was held by a master in lunacy on the request of the family, but by the time it was held there was no evidence to produce of existing insanity. Three months later ordinary work was resumed in London and at the end of another three months the patient, remaining perfectly well mentally, was also discharged recovered.

CASE 3.—This case was of about six years' duration and during a considerable portion of the time the disease was in a state of arrest.

West Malling, Kent.

AXIS-TRACTION FORCEPS.

BY WALTER COLQUHOUN, M.A., M.B., C.M. GLASG.

THE matter of this paper, the subject of which has caused me considerable thought, may not appear inopportunely at the present moment, when so many busy practitioners are giving up their old forceps for forceps guaranteed to pull in the direction of the pelvic axis. If I may seem to some readers to deal with points which have been thrashed out elsewhere at greater length my answer is that they did not seem to be known to able practitioners, my friends, and, further, that they have evidently been missed more or less by inventors whose forceps are in good enough repute. Dr. Playfair pertinently remarks concerning forceps: "It would be a wearisome and unsatisfactory task to dwell on all the modifications of the instrument which have been made, which are so numerous as to make it almost appear as if no one could practise midwifery with the least pretension to eminence unless he has attached his name to a new variety of forceps." Nor can it be expected that those who dwell in the valleys will altogether escape the epidemic ranging among dwellers on obstetric heights. In many a humble medical home in Scotland some secluded cupboard contains weapons which may probably be hung on the walls by female posterity and be pointed to with pride as relics of the battle of Bannockburn. I also invented a beautiful pair of forceps, superior to anything in existence, but convalescence fortunately setting in while the matter was at the paper stage I began to consider the essentials demanded from axis-traction forceps, and also how those demands are met by the various forms in use. It is my purpose in this paper to deal with the general question from that point of view.

A pair of forceps is said to act in three ways: (1) as a tractor; (2) as a lever; and (3) as a compressor. An axis-traction forceps (since it is inconvenient to use two different pairs in the same case) should combine these three properties with that of confining traction at each point to the direction of the pelvic axis. To these properties attempts are now made to provide for free movement of the fœtal head in flexion, extension, and rotation, and in addition it is demanded that the forceps should act as a guide to the fœtus and as an indicator of the direction of traction. Let me consider the points in detail.

Direction of traction.—In many instruments the forceps are used, but used erroneously, as an indicator of the direction in which traction should be made; that is to say, the pelvic curve of the instrument is considered to coincide with the pelvic axis, and traction being made on the instrument after locking by means of a tractor which enables it to swing more or less freely it is supposed to slide out keeping to the pelvic curve. The instruction given with most instruments is that the bar of the tractor should be kept parallel to the handles of the forceps. Now, to pull in the direction of the axis the pull must be given at each instant in the direction of the tangent to the pelvic curve at the point where it passes the centres of the fenestræ. Accordingly, if it is intended to use the handles of the forceps as an indicator of the direction of traction they should be bent backwards. A glance at Tarnier's excellent instrument will show that the part of the forceps corresponding to the handles of our instruments is practically parallel to the curve at the centre of the fenestra. In Neville's forceps also, Rotunda pattern, an arrow indicates the direction of pull which is inclined backwards from the handles. In connexion with this point the following quotation from Barnes's "Obstetric Operations" is interesting: "Dr. Aveling curves the handles of a short double-curved forceps backwards, thus increasing, he affirms, the tractile power." Here the idea does not seem to have been to change the direction of the pull, but rather to approach the point to which traction was applied to the line representing the axis, just as is done in axis-traction instruments by curving the traction rods backwards. The direction of traction altogether depends on the direction in which the pull is made and not at all on the point at which it is made. Thus it is of little use to curve the traction rods backwards if the pull is in the wrong direction. They are curved backwards because the forceps and the child's head forming a rigid lever, the fulcrum of which is above the point of application of the forceps, if any force be applied in a given direction to the handle of the forceps the point of application of that force tends to lie on a line drawn through the fulcrum in the given direction. Hence the application of a force at the handles of the forceps, even when applied in the right direction, may wrongly cause or prevent flexion or extension, or, what is of more serious consequence, may press the forceps and head injuriously against the soft parts of the mother. The curving of the traction rods backwards tends to place the point of application of the pull on the line of direction of the force which passes through the fulcrum. If this condition be satisfied and the pull be at each instant in the right direction it is of little importance whether the traction rods be attached high up or not.

Rotation, flexion, and extension.—Why, then, is it asserted to be a distinct advantage in practice to have the traction rods attached high up? I have heard it asserted that such an arrangement allows of free flexion or extension, but I hope to show presently that there is little truth in the assertion. If there is any advantage in the high insertion of the traction rods it seems to me to lie in the fact that such an arrangement allows the forceps to act as guide to the fœtal head more easily and tends to minimise the disadvantage accruing from wrong application of force at the end of the long rigid lever formed by head and forceps. Flexion and extension occur at the proper stages during delivery by rigid forceps and as a matter of necessity. It is claimed that some of the recent axis-traction forceps by allowing the forceps to swing about the points of application of the traction rods allow free flexion and extension and yet the inventors of the instruments use them as indicators of the direction of traction. As a matter of fact, forceps which fit the pelvic curve and are rigidly connected with the fœtus can have no free swing, and flexion and extension, except within

Digitized by Google

very small limits, occur at the same places during delivery and in the same manner as when rigid forceps are used, traction being applied by the handles. Thus extension, for example, could take place without advance of head and forceps only by the forceps leaving the pelvic curve.

A point which is not much dwelt on by inventors is that forceps which are best suited for axis traction, having a full pelvic curve, are unsuited for rotation and that if they rotate they are no longer axis-traction forceps. Indeed, the only way to restore true axis traction in such cases would be to take them off after rotation and obtain a new grip. Forceps with a pronounced pelvic curve are evidently intended to be put on in the transverse diameter, and if rotated to any extent the pelvic curve is no longer a guide or indicator but rather a hindrance. Hence the wisdom shown by Simpson in making his forceps with a modified pelvic curve to allow of some rotation and slight movement of flexion or extension. It seems to me a problem worthy of grave attention whether for general use the axis-traction forceps coming so much into vogue are not more dangerous than Simpson's long forceps used with some knowledge and caution. Rigby in his "System of Midwifery" says: "The forceps is the simplest imitation of nature, for, in fact, it is nothing more than a pair of artificial hands introduced one on each side of the head." Now when a man grasps the handles of the forceps the instrument may be regarded as a continuation of his own hands. There is direct connexion between his hands and the fœtus, he feels when it moves or yields, estimates more accurately the force he is using, and by his great leverage can, guided by his knowledge, help its progress at a difficult point. Using the axis-traction forceps is like putting another man's hands into the pelvis to grasp the head and then pulling on his coat-tails. I am so convinced o the advantage of a rigid connexion with the fœtus that, apart from other considerations, I consider that to be one of the advantages of Murdoch Cameron's antero-posterior forceps. It is quite common for medical men to complete delivery by pulling on the traction bar. Now I confess that if the head is high in the pelvis, and indeed until it has reached the floor, it is of advantage to have an indicator of the direction of the axis and also the power of pulling freely in the direction of the axis, but I am of opinion that in every case both hands should be used, one grasping the handles of the forceps and the other the traction handle. The hand which grasps the handles of the forceps can apply leverage where necessary, steady the progress of the fœtus, and obtain information of that progress which would not be obtained by merely pulling on the traction handle. When the head has reached the floor of the pelvis it is especially necessary, for the sake of the perineum, among other reasons, to complete delivery without having recourse to the traction handle. In his "System of Midwifery," 1844, Rigby writes: "In extracting the head we must bear in mind the part of the pelvis in which it is impacted and make our efforts in the direction of its axis; we must also recollect the curved form of the instrument, and that we must not pull in the direction in which the handles point, *but rather hold them firmly in one hand and by pressing against the middle of the forceps with the other guide the head downwards and backwards into the cavity of the pelvis.* We shall thus make our extractive effort in the direction of the upper portion of the blades, or that part which has the chief hold upon the head." (The italics are mine.) Here there is perfect axis traction arranged for without any great apparatus but simply by means of the ordinary forceps used with the good sense and ingenuity of a practical man, and his axis traction would be much more perfect than that of a practitioner who delivered by simply pulling on the traction handle of one of the latest instruments. Traction rods enable the operator to use the second hand to great advantage, but the more important hand is the one which grasps the handles of the forceps. The forceps in Rigby's hands had another important use, for he continues: "Whilst extracting we should, as with the straight forceps, slowly move the handles from side to side and even make them describe a circle. We thus not only use the forceps as a simple extracting instrument, but make it act as a lever in every direction and greatly facilitate the advance of the head, even under circumstances of considerable impaction."

It was the considerations I have set forth which caused my forceps to be stillborn. I was providing for free movements of rotation, flexion, or extension, by placing immediately below each fenestra a swivel and a hinge, which could both be unlocked from the handles. I am now convinced that while it is a benefit to be able to use the curved traction rods, the rigidity of the instrument and its simplicity should be interfered with as little as possible.

Glasgow.

PARALYSIS AGITANS;

WITH AN ACCOUNT OF A NEW SYMPTOM.

BY PURVES STEWART, M.A., M.D. EDIN., M.R.C.P. LOND.,

SENIOR HOUSE PHYSICIAN TO THE NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, QUEEN-SQUARE, BLOOMSBURY, LONDON, W.C.

EIGHTY years ago Parkinson wrote his classical description of paralysis agitans. So little has been added to its symptomatology since and the disease now appears at first sight to be, clinically at least, so thoroughly worked out that to many it may seem a superfluous task to traverse once more a subject so well worn. The following paper, therefore, must be regarded as merely supplementary to the descriptions in the text-books, not in any sense as a substitute for them.

Within the past two years I have had opportunities of studying a number of patients, 28 in all, suffering from paralysis agitans and it is upon personal observations on these cases that the following remarks are based. Although the number of cases is not large enough to permit of any statistical references being founded upon them alone, yet the fact that they have been examined and compared by one person renders the value of the observations fairly uniform, whilst the cases are sufficiently numerous to justify me in drawing certain clinical conclusions. Of these 28 cases, 17 occurred in men and 11 in women. This greater frequency among male patients is in entire agreement with the combined statistics of a large number of cases seen by other physicians, which show the disease to be much more frequent in the male sex than in the female, the proportion being about 2 men to 1 woman.

The age of onset of symptoms in my series of cases is instructive. It ranges from twenty-two years to seventy-three years, the distribution being as follows:—In 1 case the earliest symptom appeared at the age of twenty-two years; in 1 case at thirty years; in 1 case at thirty-three years; in 2 cases between the ages of thirty-five and forty years; in 3 cases between forty and forty-five years; in 6 cases between forty-five and fifty years; in 7 cases between fifty and fifty-five years; in 4 cases between fifty-five and sixty years; in 2 cases between sixty and sixty-five years; and in 1 case at the age of seventy-three years. Thus 23 cases out of 28—i.e., over 82 per cent.—commenced after the age of forty years.

A family history of nervous disease was obtained in only a few instances (in 6 cases out of 28). In 4 of these 6 cases there was epilepsy or insanity in the patient's brother or sister; in 3 of the 6 cases a relative had actually suffered from paralysis agitans—a maternal aunt in one case, a paternal grandfather in another, and a sister in a third. As to exciting cause, 6 patients gave a history of fright or emotional disturbance. Thus, for example, in one case the earliest symptom—shaking of the left thumb—showed itself after a shock occasioned by a sister becoming insane. Another patient was at a menagerie when a lion escaped from its cage and caused considerable alarm amongst the spectators. On the next day the patient's illness is said to have commenced, his first symptom being stiffness of the left leg. Another patient was threatened as a "blackleg" by his fellow-workmen on the railway who were on strike and ever afterwards he found his right hand stiff and his handwriting unusually slow. Another patient blamed the shock of having a tooth extracted as being the antecedent cause of her illness, the earliest symptom in her case being tremor of the left hand. Worry or overwork was assigned as the exciting cause in 3 cases; 3 were said to have followed an attack of influenza; and one patient had an attack of right hemiplegia a few weeks before the tremor of paralysis agitans appeared in his left hand. One man had his foot trodden on by a horse a year before the onset of tremor in that foot. One woman's symptoms came on after a confinement at the age

Digitized by Google

of forty-six years and another patient sustained a fall which is said to have produced a prolapse of the uterus and this was succeeded by stiffness of the legs. In the remaining 12 cases no cause was assigned by the patient in the form of injury, emotion, or preceding disease. Moreover, the severity of the disease in those cases where some exciting cause was ascribed was not at all proportional to the intensity of the assigned cause. It therefore seems probable, on the whole, that such so-called exciting causes, if they really are causes at all, merely precipitate the disease in a decaying nervous system.

The earliest symptom in a large proportion of my cases was not tremor but stiffness—contrary to the orthodox statements of the text-books. In 14 cases out of 28 stiffness and weakness preceded the tremor for periods varying from several weeks to over two years, and in 3 of these cases tremors were entirely absent although the disease had been well established, with its characteristic attitude and facial expression and with a definite history of stiffness and weakness, for fifteen months, eighteen months, and four years respectively. In 3 other cases, again, tremors only occurred on excitement or on voluntary effort, the patients exhibiting no tremor whatever when at rest. The dictum that the tremors of paralysis agitans are diminished by voluntary movement can therefore no longer be accepted as an invariable rule, nor as a secure point of diagnosis between paralysis agitans and other diseases.

The symptoms of the disease in most cases are hemiplegic in distribution. In only 2 cases out of 28 were the limbs of both sides equally affected. The left side appears in the majority of cases to be affected before the right, in right-handed people. Thus 14 cases began on the left side and only 12 on the right, and one of these 12 was in a left-handed man, so that his case should be properly added to the 14 left-sided cases. That side which is first attacked remains, as a rule, more severely affected than the other side even when, later in the disease, the symptoms have become bilateral. The upper extremity was affected before the lower in 18 cases out of 28 and the hand usually suffered before the shoulder, though not invariably. Thus one patient, a woman, first felt her left hand weak and stiff when peeling potatoes, so that she had difficulty in turning the potato round. Another patient, a professional musician, first noticed weakness in her left hand when playing the organ. Several patients noticed, as their earliest symptom, an abnormal slowness in writing; another patient first experienced inconvenience from the tremor of his fingers owing to a difficulty in buttoning his clothes. In only one patient did the weakness begin in the shoulder—his attention being attracted by the unusual difficulty which he experienced in putting on his overcoat.

The orthodox clinical picture of a patient suffering from paralysis agitans is too well known to require much emphasising here. In a fully developed "classical" example of the disease the constant rhythmic tremors of fingers and wrists, the "interosseal" position of the fingers, the stooping attitude of the head and trunk, the "festinant" gait with its short, shuffling steps, the retropulsion on walking backwards, the difficulty in rising from the sitting to the standing posture, the tremors of the legs when sitting down, the slowness of voluntary movements in trunk and limbs, the fixed and sad facial expression,—all these, when present, form a striking clinical picture which it is easy to recognise. But such a condition of affairs is only reached when the malady is far advanced and we ought to be able to recognise its nature long before the disease has attained such severity as to be diagnosable telescopically.

Let us therefore consider some of the symptoms of the disease more in detail. The prevalent conception of paralysis agitans is that of a disease in which sensory symptoms are practically almost absent. Such, however, is not the case. Dull, aching pains in the affected limbs, along with a feeling of stiffness and weakness, often precede for a long time the actual rigidity or tremor. The patients also frequently complain of sudden flushes of heat or of cold spreading all over the body, especially at nights when in bed. As mentioned above, a case of paralysis agitans may run its course for years without any visible tremor whatsoever, this being the so-called "paralysis agitans sine agitatione." One reason why this variety or stage of the disease is not more generally known is because the real nature of the malady is usually not recognised until obvious tremors have appeared. As to motor symptoms, the presence of stiffness and rigidity should suggest paralysis agitans almost as readily as does the existence of visible rhythmic tremors. In paralysis agitans all voluntary movements may become slow and stiff, with a few notable exceptions, as in the ocular, palatal, and respiratory muscles. In a well-marked case, if the patient be requested to look suddenly at some object near the extreme lateral boundary of his field of vision, he turns his eyes smartly in the desired direction whilst his head and neck follow slowly and deliberately in the movement of rotation. Why the ocular muscles should usually escape it is difficult to explain, since almost all the other voluntary muscles of the face, trunk, and limbs may be affected, certainly by rigidity and often by tremor as well. Rhythmic tremor of the jaw occurred in 4 of my cases, the movement of the jaw being an up-and-down one and synchronous with the rhythmic movement of the limbs.

The face is characteristically affected, and in a well-marked case in which both sides of the face have become affected the result is the "Parkinsonian mask" in which the expression is fixed and woe-begone; it has been aptly termed the "starched" expression. In this condition the facial immobility is such that when the patient is talking his play of facial expression is almost *nil*, the deficiency being evident both in the upper and in the lower facial muscles. The condition can be most strikingly demonstrated by covering up the patient's chin and lower lip whilst he is talking. It is then often remarkable how motionless is the upper part of the face above and including the upper lip. And this "starched" expression of face may be unilateral, as will readily be understood when we remember the frequent hemiplegic distribution of the disease. Thus out of 11 cases which exhibited the phenomenon in no fewer than 9 the facial movements were distinctly asymmetrical, the weakness being most marked in the lower facial muscles and always on the same side as that on which the limbs were affected, the difference between the two sides of the face being best brought out when the patient was made to retract the upper lip, the naso-labial fold in such cases being distinctly shallower on the weaker side. In some cases (6 in my series) the face is not merely immobile but may actually develop rhythmic tremors, especially about the lips, and in 3 cases this was associated with a synchronous antero-posterior tremor of the tongue. The voice is often high-pitched and monotonous and its quality is frequently thin and quavering. The soft palate was not affected by tremors in any of my cases. Articulation is frequently disturbed, tending to assume a "festinant" character. The patient starts off deliberately enough at the beginning of a sentence, but after a few words the syllables become slurred and jumbled together, so that in some cases the concluding words of each sentence are almost unintelligible.

As regards the trunk and limbs the characteristic stooping attitude and the frequent rhythmic movements are so familiar that they need not be described here in detail. But one remark may be added—viz., that the attitude of the patient, the "interosseal" position of the hand, the semi-flexed, pronated forearm, the frequently unilateral facial weakness, most evident in the lower facial muscles, the stiff, shuffling gait, often more marked on one side than on the other,—all these, as has been pointed out by Dr. Hughlings Jackson, closely resemble the attitude seen in ordinary hemiplegia due to a cerebral lesion.

Another symptom, which is seen only in advanced cases accompanied by much rigidity, consists in a peculiar method of assuming the recumbent attitude. The patient, instead of lying down in bed in the usual way, climbs up on to the bed and stands on it. Then bending down very slowly he takes hold of the rail at the foot of the bed with both his hands and gradually sits down on the bed, holding on to the rail all the time. Having in this manner reached the sitting posture the patient then allows his trunk to fall backwards into the recumbent posture. This circuitous method of getting into bed is characteristic of the disease. A somewhat similar affection is described below (*vide* Case 3). Difficulty in changing the position when in bed is a common symptom and patients frequently complain, in addition, of a difficulty in finding a comfortable position when lying down. This feeling of restlessness is interesting when we remember the muscular rigidity which accompanies it.

In concluding this paper I should like to call attention to a new symptom which has not hitherto, I believe, been placed on record. As might be expected, it is a minor symptom, but in my series of cases it occurred no fewer than five times—i.e., with sufficient frequency to place it beyond

Digitized by Google

the category of mere coincidence. It consists in a peculiar affection of the toes, which in the majority of the cases in which I have met with it was one of the earliest symptoms of the disease, and is therefore, I think, of considerable diagnostic value. It is as follows. The patient complains, when walking, that the toes of one foot occasionally become spontaneously strongly flexed and curled up under the sole in a cramp-like fashion, causing difficulty in walking. This "curling up" of the toes is often so uncomfortable that the patient has to stand still for a minute or two until he can get his toes to relax and spread out flat again. All the toes, with the exception of the great toe, participate in this flexor contracture; the hallux, on the other hand, usually becomes hyperextended at the same time; sometimes, however, it may become flexed like the other toes. In some cases the contraction may spread to the anterior tibial muscles, causing an inversion of the ankle as well. For permission to publish my notes I am indebted to the courtesy of Dr. Hughlings Jackson, Dr. Buzzard, Dr. Ferrier, and Dr. Ormerod.

CASE 1.—The patient, a man, fifty-four years of age, was admitted to the hospital on Dec. 13th, 1896. Six months before his admission, when walking, he began to feel the toes of both feet become occasionally hyperextended, this movement passing on at once to one of plantar flexion. His ankles also became dorsiflexed, so that he had to take a step or two backwards until the cramp passed off. Two months after the onset of this symptom his hands became stiff and weak and his handwriting became abnormally slow. On admission he had the typical facies of paralysis agitans—the starched expression, the stooping of the head, the elbows slightly flexed, the fingers in the "interosseal" position, no tremor either at rest or on movement, and all voluntary movements slow and stiff.

CASE 2.—A man, forty-two years of age, was admitted to the hospital on Feb. 9th, 1897. For four years before his admission he noticed that the toes of his right foot would occasionally become strongly flexed when he walked so that he had to stand still until his toes relaxed. Later his right leg became stiff and weak and his right hand became slow in its movements so that he could not cut his food readily nor could he write so easily or so rapidly as usual. Within the last three or four months he had developed slight tremor of the right foot when fatigued. On admission he had slight weakness and rigidity of the right face, arm, and leg, with marked "starched" expression. The right hand was held in the "interosseal" attitude and the right elbow was habitually semi-flexed. All movements of the right arm and leg were slower and stiffer than on the left side. He dragged his right foot a little in walking; there were no tremors on admission. He complained of difficulty in turning in bed and in finding a comfortable posture when in bed.

CASE 3.—A married woman, aged fifty years, was admitted to the hospital on June 14th, 1898. For three years she had had trembling of the left hand and arm followed, some six months later, by trembling of the right hand, which she first noticed when putting pegs on a clothes-line. For two years she had had difficulty in turning in bed and had been unable to get into or out of bed without assistance owing to stiffness of her legs. About a year before admission she began to feel her toes curling up under her soles inside her shoes when she was sitting down. This made her get up and walk about for a few minutes until the symptom passed off. She had been unable to sing for a year; within the last month or so her jaw began to tremble and her articulation became less distinct. On admission she was seen to have severe paralysis agitans with the typical "starched" face, the typical attitude of the limbs and trunk, and tremors of the face, jaw, tongue, and limbs, synchronous, the rate of tremor being 6 per second. The tremors affected the limbs equally on the two sides. Her articulation was markedly festinant and her voice was monotonous and plaintive. All voluntary movements of the trunk and limbs were slow and stiff and the tremor persisted in spite of voluntary movement. The gait was slow and shuffling and there was no festination; she could not turn round without holding on to the furniture. She could not feed herself owing to tremors. She was unable to lie down in bed herself. When trying to do so she put one knee on the edge of the bed and then fell heavily on to the bed in a semi-prone posture, from which she was unable to move without assistance. She perspired excessively and would not allow herself to be covered by more than a single sheet.

CASE 4.—A married woman, aged fifty years, was admitted to the hospital on March 1st, 1897. Her mother's sister had paralysis agitans. Four years previously, a fortnight after her last confinement, the patient noticed tremor of the fingers of the left hand on movement. Stiffness of the left arm and later of the left leg had since developed. Within the last two years the right side had become stiff, the arm being affected before the leg. For about two years she had noticed in walking that the toes of both feet occasionally curled under the soles, except the big toes, and she had to stand still for a few minutes until this passed off. She had had great difficulty in turning in bed for the past six months. On admission she had the typical face of paralysis agitans, "interosseal" attitude of the hands, stooping head, festinant shuffling gait, and marked retropulsion. The speech was monotonous and festinant. All the voluntary movements were slow and stiff, especially on the left side. She had difficulty in doing her hair herself; she could not use her left hand easily to "gather" the hair. There was very slight tremor in the left hand, this occurring only on holding it out, not when it was at rest.

CASE 5.—A man, fifty-three years of age, was admitted to the hospital on Dec. 4th, 1896. He was left-handed. For four years he had noticed that the toes of his right foot occasionally became stiffly flexed into the sole; the hallux, however, became hyperextended. About two years previous to his admission he began to have slowness and tremor in writing with the right hand, and about a year afterwards his right leg began to shake, especially in walking. On admission he had the typical symptoms of paralysis agitans in the right face, arm, and leg, there being both tremors and rigidity. The gait was shuffling but not festinant. He could voluntarily stop the tremors for a moment.

In 3 of the above 5 cases the "toe-curling" symptom was the earliest to appear, preceding the other symptoms by intervals of four months (Case 1), a year (Case 2), and two years (Case 5) respectively.

Since the above paper was written I have been kindly favoured by Dr. Ormerod (to whom I had mentioned this symptom) with the notes of another corroborative case in which the patient, after having had the "toe-curling" symptom for five years, developed symptoms of paralysis agitans.

CASE 6.—The patient, a man, aged forty-four years, consulted Dr. Ormerod in March, 1892, for a "drawing under of the toes of the left foot. This came on chiefly after walking, all the toes becoming flexed, beginning with the big toe and then the ankle becoming inverted. The symptom had been present since 1890. Dr. Ormerod writes: "At that time I do not think there was anything in his symptoms or general appearance to make me suspect that he had paralysis agitans. In May, 1895, he came again and there was no doubt that he now had paralysis agitans. There were characteristic tremors of both hands and the facies was that of paralysis agitans; the gait was not very characteristic. The affection of the left foot still continues; it looks shorter and more humpy than the right."

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

TWO CASES OF PUERPERIUM COMPLICATED WITH SCARLET FEVER; RECOVERY.

BY J. GAWLER MURRAY, L.R.C.P., L.R.C.S. EDIN., L.F.P.S. GLASG.

THE following cases may be of interest, showing that pregnant women seldom develop scarlet fever (Haultain).

CASE 1.—I attended the patient on May 24th. The child was born on my arrival and the placenta came away quite easily. I visited the patient on the 26th, 27th, and 28th, her temperature never being above 99·2° F. On the 29th I found her looking very ill and with a temperature of 105°. I immediately douched out the uterus with iodine and water and ordered the nurse to give a vaginal douche of weak Condy's fluid every two hours as the discharge was very foul-smelling. I called in the afternoon to repeat the intra-uterine douche and found the patient's temperature to be

Digitized by Google

105·8°. On calling in the evening her temperature was found to have fallen to 103·4°, but I repeated the douche of iodine. The temperature on the next morning was 102·4° and the patient was found to be covered with a typical scarlatinal rash and she complained of sore-throat. My father (Dr. Ivor Murray), whom I called in, confirmed my diagnosis and notified scarlet fever. On making inquiries I learnt that two children of the previous tenant of the house had had scarlet fever there in the previous October; the patient and her husband came into the house in November. This was the only clue to contagion which I could get, as the patient had not been near any scarlet fever cases and I had not myself seen any for six months previously. This, I think, points to the indefinite incubation period of scarlet fever in pregnant women. The baby also took the infection, but both mother and child made uninterrupted recoveries, both desquamating freely.

CASE 2.—A sister-in-law of the above patient who was in daily expectation of being confined and who lived next door had, of course, seen her sister and the baby before I had any suspicion of anything being wrong, but when the temperature of the first patient rose I forbade her sister-in-law to enter the house, and at the confinement of the latter on June 5th I took every precaution and was careful to put on fresh clothes. On June 8th, however, the patient's temperature ran up to 104° F., and she had a strawberry tongue and sore-throat, but there was no definite rash. Knowing that she had been exposed to contagion I treated her as for scarlet fever. In spite of diaphoretics, quinine, Warburg's tincture, &c., her temperature oscillated between 101° and 104° for fourteen days, when it went down to 99°. Owing to sleepless nights I had given trional (20 gr.) with good result, but on the 23rd I found that she had taken a violent dislike to nursing her baby and to her husband and that she fancied herself to be a feather and that she would blow away. On the 25th she complained of her left arm being swollen and on examination I found a hard lump in the axilla. I wrapped the arm in wool and kept her quiet, but it swelled to twice its size till under massage it gradually decreased. Her urine contained a slight amount of albumin and her legs were slightly swollen, but as she recovered strength her urine became normal. She desquamated very slightly. The mania lasted about a fortnight and she is now as strong and well as ever she was. This case I think interesting because of the number of complications which had to be contended against.

Scarborough.

A NOTE ON AMPUTATION FOR CHARCOT'S JOINT DISEASE.

BY F. A. SOUTHAM, M.B. OXON., F.R.C.S. ENG.,
SURGEON TO THE MANCHESTER ROYAL INFIRMARY; LECTURER ON OPERATIVE SURGERY, OWENS COLLEGE.

ABOUT six years ago a case of Charcot's joint disease came under my care in which the ankle-joint had become so completely disorganised that the foot was displaced upwards and outwards, the internal malleolus projecting prominently through an opening in the skin; in fact, the appearance was not unlike that met with in an unreduced compound Pott's fracture. Removal of the foot was the obvious treatment, but in the absence of any definite information on the question of amputation in patients suffering from Charcot's joint disease, and, bearing in mind the unsatisfactory results which often follow amputation for perforating ulcer in tabetic subjects, I was hesitating somewhat as to the advisability of adopting this course, when a short article by Mr. Jonathan Hutchinson, published a few months previously in the Archives of Surgery,[1] attracted my notice. Mr. Hutchinson wrote as follows: "I have recently had an opportunity of observing the process of repair after amputation in a state of advanced locomotor ataxy. It may be of interest to record the result, since, owing to absence of any experience on the point, I felt some misgivings in recommending the measure." Details were then given of the performance of Teale's amputation in a middle-aged subject who for ten years had suffered from locomotor ataxy accompanied by perforating ulcer and disease of the bones of the foot and ankle-joint. The result of the operation was extremely satisfactory, the patient recovering with a sound stump, which was afterwards fitted with an artificial limb and bore pressure well.

Encouraged by Mr. Hutchinson's success I advised my patient, a male, aged forty-nine years, to submit to amputation of the leg below the knee-joint, and to this he readily consented, being anxious to be rid of the foot, which, though it caused him no pain, had become a great inconvenience to him. Since then I have performed the same operation in three other patients, all males between forty and fifty years of age, for a similar condition, the ankle-joint being affected in one case and the tarsal joints in the other two. In all four patients the result has been most satisfactory, the stumps healing quickly without suppuration and without any tendency to sloughing of the soft tissues or necrosis of the end of the bone, as might have been expected from the nervous origin of the disease.

It is somewhat strange that in most works on surgery little or no reference is made to the question of operation in cases of locomotor ataxy when a joint has become completely disorganised. In a recent text-book the following paragraph, however, appears: "In the later stages, where the joint is entirely disorganised, some form of fixed apparatus may be applied to render the limb more useful, since no operative treatment can be undertaken."[2] A similar opinion is expressed in one of the most recent German works on nervous diseases, for it is there stated that though the joint affections may require some mechanical support surgical treatment is seldom necessary, operative interference being avoided by most surgeons.[3]

NOTES ON A CASE OF PERSISTENCE OF HYMEN; NON-RUPTURE.

BY N. CULLINAN, M.D. BRUX.

THE following case having come under my notice may be of interest to the readers of THE LANCET from a medico-legal point of view as well as on account of the obstruction which may be caused during the second stage of labour.

On March 13th, 1898, I was called to attend a primipara, aged twenty-five years. On making my visit and questioning the midwife I found that the patient had been in labour for nine hours, the pains then recurring about every seven minutes. On attempting to make a vaginal examination I found that an obstruction existed and the parts were tender to the touch, which latter sensation lasted a considerable time. Having determined the position of the fœtus by an abdominal examination I resolved to await results. The labour progressed naturally until a fulness could be noticed in the perineum. A visual examination now confirmed the conclusion which I had previously arrived at; the membrane was intact except for a small opening which would allow the escape of the menstrual fluid, situated in the antero-posterior line about one-third from the anterior and two-thirds from the posterior edge of the vaginal opening, the aperture being of sufficient size to admit an ordinary slate-pencil. The clitoris was of abnormal length and sensitive. On attempting to enlarge the opening in the hymen with the tip of the little finger the patient complained of intense pain and I decided to desist. I then used a hernia knife, making a crucial incision, and the succeeding pain caused the protrusion of the membranes well into the opening made. After making a vaginal examination and allowing the liquor amnii to escape the labour terminated naturally, no laceration taking place. The patient made a good recovery.

The points of interest in this case are as follow: (1) the non-rupture of the membrane although the patient had been married for eleven months; (2) the membrane itself was of a fibro-elastic consistence and extremely dense; (3) the small opening allowing impregnation to take place; (4) the abnormal sensitiveness of the parts; (5) an unusually large clitoris; and (6) the obstruction caused during the second stage of labour with the amount of force necessary to cause rupture. From a medico-legal point of view cases of this sort are of much importance showing that impregnation can take place without rupture of the hymen, that the presence of the membrane is not a positive proof

Digitized by Google

of virginity, and therefore it behoves a medical witness to be careful in giving an opinion, for if he swears that a woman is a virgin and later she turns out to be pregnant he may involve himself in legal proceedings as well as perhaps the loss of his reputation. On the other hand, the absence of the hymen does not prove that defloration has taken place. Such a condition may exist from ulceration, masturbation, &c.

Pontymister, Monmouthshire.

NOTE ON STAINING THE CAPSULES OF PNEUMOCOCCUS AND OF THE BACILLUS OF FRIEDLÄNDER.

BY ALFRED MACCONKEY.

(*From the Bacteriological Laboratory of Guy's Hospital.*)

RIBBERT'S observation that dahlia is useful for staining the capsules of pneumococcus has not met with the attention it deserves, as there are very few references to it in the text-books. Dahlia stains the cocci well and their capsules faintly. Bleu de Roux (dahlia with methyl green) gives a better result when slightly warmed; and the addition of fuchsin effects a still further improvement. The following combination gives a clear image which photographs well: dahlia, 0·5 gramme; methyl green (0 0 crystal), 1·5 gramme; saturated alcoholic solution of fuchsin, 10 c.c.; distilled water to 200 c.c. The dahlia and methyl green are rubbed up in a mortar with part of the water until dissolved, then the fuchsin is added, and finally the rest of the water.

Staining.—Prepare the film in the usual way. Flood the cover slip with the stain and hold over the flame until steam begins to rise. Then place aside for about five minutes, wash in water, dry, and mount in xylol balsam. N.B.—If the film is treated with acetic acid before staining the result is not so good.

This serves as a good general stain and gives good results with the bacillus typhi abdominalis, bacillus coli communis, and especially with the Klebs-Löffler bacillus.

UNIVERSITY COLLEGE HOSPITAL.

A CASE OF INTUSSUSCEPTION TREATED BY LAPAROTOMY; RAPID RECOVERY.

(Under the care of Mr. RICKMAN J. GODLEE.)

WE have recently[1] published cases demonstrating the value of early operation in intussusception, but the importance of adopting this method of treatment could not be more satisfactorily demonstrated than in the case reported below. The early age of the patient and the severity of the symptoms would soon have led to a fatal termination, and the difficulty with which the bowel was reduced by manipulation renders it impossible to believe that any form of injection or inflation could have effected the reduction. But inflation has dangers of its own: it has led to rupture, it may appear to succeed though the bowel is still tightly grasped, and by its use very valuable time is lost. For these reasons, and in view of the results obtained by laparotomy in many cases, it can now hardly be maintained that inflation is justifiable, except in cases where the parents refuse to allow a cutting operation. In Mr. Godlee's case the patient was only six months old, and though recovery has been recorded in several instances at an earlier age, yet it is noteworthy how rapidly the child recovered, for he was discharged perfectly well on the seventh day. For the notes of the case we are indebted to Mr. Montague Dixon, house surgeon.

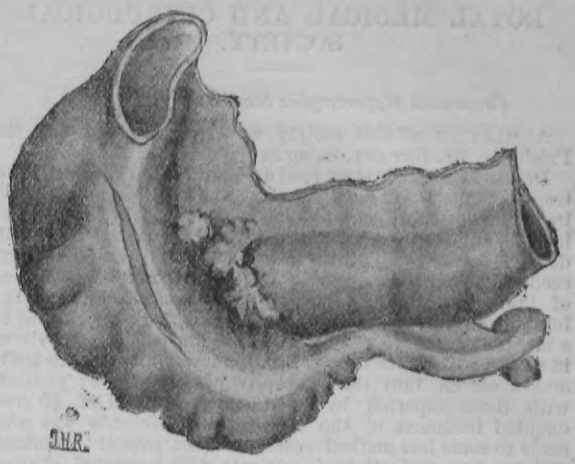
A male infant, aged six months, was taken by his mother to the out-patient department of University College Hospital at midnight on Sept. 28th, 1898. The history given by the mother was that at six o'clock that evening the child vomited and that the vomiting was repeated at intervals until about 10.15 P.M., when he passed "some blood and slime from the back passage." He had been crying a good deal and had been restless, drawing the legs up and appearing to be in pain. The infant was doubly ruptured, was breast-fed, and had had no previous illness. On examination he was seen to be a fine fat child. He was pale and seemed to be in pain. The knees were drawn up and there was evidently abdominal pain. The pulse was small and rapid. On palpation of the abdomen some tenderness was evident and the child showed his resentment by crying. Passing from the right side just below the costal margin to the epigastrium a sausage-shaped, curved tumour was felt characteristic of an intussusception. It moved with respiration, and palpation of it caused more screaming than palpation of the rest of the abdomen. Rectal examination revealed nothing. The abdomen was cleansed and disinfected and the child's limbs and chest were bandaged in wool. Chloroform was administered and the abdomen was opened by a longitudinal incision about 2 in. in length just above the umbilicus and a little to one side of the linea alba. On drawing out the transverse colon a large intussusception was seen. The greater part of this was very easily and rapidly reduced by the ordinary manipulation, but the reduction of the last part was difficult. Of this last part the lower few inches of the ileum and the first portion of the ascending colon with the cæcum formed the intussusceptum, while the remainder of the ascending colon constituted the intussuscipiens. On firm pressure no effect was produced for a moment, when suddenly the reduction began to be effected and the portion of large intestine forming the intussusceptum shot out and became the intussuscipiens, leaving therefore only the lower few inches of the ileum as intussusceptum. On continued manipulation this also was reduced, completing the reduction. The portion of ileum which had been invaginated was remarkably stiff and inelastic owing to exudation into its substance, and remained out of shape while under observation, forming a sort of flat, oval tumour about 2 in. long by 1 in. wide. The whole bowel was, however, in good condition, the circulation throughout being maintained. The appendix was found to be quite normal and not even congested. The case was therefore of the ileo-colic variety. On the next day (Sept. 29th) the patient was doing splendidly. The mother continued to suckle him. He had vomited twice during the night. The temperature was 100·8° F. and the pulse was 168. No flatus had been noticed. At night the child vomited once and passed a stool containing a little blood and mucus. The stool was not green but was darker than normal and rather watery. The temperature never rose again as high as 100·8° during recovery. The patient was discharged on Oct. 4th, having been in hospital six days, and he had recovered completely from his trouble.

Remarks by Mr. GODLEE.—The case demonstrates the advantage of early operation. Had inflation been tried the modification in the shape of the tumour would have suggested that reduction had been accomplished; but the operation showed that this was absolutely impossible. It was difficult to effect even at this early period after the onset of symptoms, and a few hours' delay would have probably rendered excision of part of the gut necessary.

[1] THE LANCET, July 30th, 1898, and August 20th, 1898.

SALFORD ROYAL HOSPITAL.

A CASE OF ACUTE ILEO-CÆCAL INTUSSUSCEPTION; LAPAROTOMY AND REDUCTION; NECROPSY.



(Under the care of Mr. J. H. RAY.)

THE following case is chiefly remarkable for the great acuteness of the symptoms; the intussusception commenced apparently at three o'clock in the morning, and the child died about twenty-four hours later. The younger the patient as a rule the more severe are the symptoms and the greater the probability of a fatal issue. This is due to two causes: in the first place, young children stand very badly the shock

Digitized by Google

due to the bruising of the bowel and of the intestinal nerves; and secondly, the younger the child the smaller the lumen of the gut. The fatal result in this case is no argument against operation; on the contrary, it enforces the lesson that in most cases of intussusception early operation offers the only chance of saving the patient's life. The condition found at the laparotomy demonstrated clearly that no procedure other than an operation could have reduced the intussusception; and it is highly probable that if reduction had been effected only a few hours earlier recovery would have ensued.

A child, aged nine months, was taken to the Salford Royal Hospital by his mother on April 16th, 1898, about 6.30 P.M., suffering from severe peritonism as the result of an acute intussusception. The mother gave the following history. The child had always appeared to be healthy and had required no medical treatment since birth. At about 3 o'clock in the morning on April 16th the child suddenly commenced to cry, seemed to be in great pain, and rolled about restlessly. Vomiting soon appeared as well as a kind of diarrhœa with much straining; many of the later attempts at evacuation of the bowel, however, only gave rise to a discharge of almost pure blood in varying quantity and mixed at first with mucus. As these symptoms did not abate a medical man was called in, later in the day, and he advised the removal of the child to the hospital. Mr. J. H. Ray saw the patient immediately on admission. The child, who was well nourished, looked extremely ill, with pale, slightly cyanosed face and with limbs hanging helplessly. He seemed, as was observed by a bystander, to be "too ill to cry." The abdomen was slightly tumid, and beneath the lower half of the left linea semilunaris an elastic, elongated, slightly tender swelling was to be felt, whilst another elastic mass could be made out with less distinctness about midway between the left costal margin and the umbilicus. Over the right iliac fossa there was some sinking-in and on palpation lessened resistance could be made out in this situation. A finger introduced per rectum could feel nothing abnormal, but came away streaked with blood, which was also noticed on the child's linen. A diagnosis of acute ileo-cæcal intussusception was made, and by rectal injections of olive-oil and of warm water it was attempted to reduce the swelling. This failing, and only leading to the discharge of more blood, Mr. Ray performed median laparotomy at 7 P.M., making an incision from a little above the umbilicus down to the pubic region. Through this incision it was an easy matter to confirm the diagnosis, but as it was found impossible to reduce the intussusception *in situ*, the entire tumour was brought through the laparotomy wound and surrounded by towels wrung out of hot normal saline solution. The intussusception was about 18 in. long, and owing to the attachment of the mesentery and mesocolon was coiled into nearly two turns of a spiral having a diameter of rather more than 3 in. The apex of the swelling was in the sigmoid colon but beyond reach of ordinary rectal examination. By uncoiling the swelling and so relaxing the mesentery during reduction it was found comparatively easy to express the intussusceptum from the intussuscipiens, always beginning about half an inch beyond the apex. The last few inches were somewhat more difficult to disengage owing to the presence of the twisted appendix, and when completely reduced a longitudinal rent was noticed in the serous and outer muscular coat of the cæcum and ascending colon, situated almost midway in the appendicular band, as shown in the illustration, and involving this for a distance of 1½ in. The tear did not involve the circular muscle fibres and was probably of some hours' standing, for its edges were infiltrated with blood, were swollen and slightly everted, whilst there was no bleeding from the edges at the time of reduction or later. The appendix was of medium length and provided with a well-marked meso-appendix. The cæcum was covered almost entirely by peritoneum and there was a fairly long ascending mesocolon. At the junction of the ileum and the cæcum there were some masses of subperitoneal fat, as shown in the illustration. The posterior surface of the cæcum and the colon was much congested and somewhat bruised, whilst the ileo-cæcal valves were of much increased thickness as felt through the ileo-cæcal junction. The abdomen having been sponged out in the operation area and a little iodoform and boric acid powder dusted on to the injured gut in the neighbourhood of the appendicular band the parietal wound was closed with silkworm-gut sutures and the child was sent back to bed about 7.30 P.M. There was very little sickness immediately after the operation and dilute brandy and milk were given by the mouth and retained, but the child never rallied fairly from his

The ileo-cæcal junction and appendix. Showing the rent in the cæcum and the masses of fat at the junction of the ileum and cæcum.

original condition of shock and died about nine hours after the operation. The only temperature taken, about two hours after the laparotomy, registered 97° F.

Necropsy.—An examination of the abdomen post mortem showed that there had been no return of the intussusception. The above illustration represents a drawing which was made of the ileo-cæcal segment of gut shortly after removal. It shows the longitudinal rent in the appendicular band, which was due, Mr. Ray believes, to the excessive tension on this region when inverted and lying near to the apex of the intussusception and in the immediate vicinity of the tucked-in appendix. This rent might have been caused in reduction when turning out the last portion of invaginated bowel and the appendix, but no excess of force was at any time used in reducing the swelling, and, as stated above, the character of the edges noticed at the time of the operation and the absence of any bleeding or oozing points would indicate that this lesion, as well as the bruising on the posterior aspect of the cæcum and ascending colon, were due to the force of the invagination; and they suggest how severe must be the impression on the nerves of the peritoneum by such acute cases of intussusception. An examination of the ileo-cæcal orifice showed this to be patent, though narrowed by congested mucous membrane, and there was no polypoid or other growth or foreign body within the gut to account for the immediate onset of intussusception. The appendix appeared to be quite normal in structure and its lumen was not obstructed in any way.

SOUTH DEVON AND EAST CORNWALL HOSPITAL, PLYMOUTH.—A successful bazaar was held at St. Austell, Cornwall, on Nov. 3rd, in aid of the funds of this hospital, and as a result £180 will be handed over to the funds of that institution.

WEST OF ENGLAND EYE INFIRMARY.—The annual meeting of this institution was recently held at Exeter under the presidency of the Rev. W. H. McGrath. The medical report showed that during the year 2779 patients had been under treatment, of whom 2404 had been discharged benefited. A total of 95,202 patients has been treated since the opening of the infirmary in 1808. The financial statement showed that the receipts for the year amounted to £1280 and the ordinary expenditure to £1331. Since the last annual meeting £4000 had been received towards the building fund, and as the total amount was now £7000 it was decided to immediately commence the first part of the building, which the architect estimated would cost £8500. The committee hope to receive further subscriptions so as to enable them to carry out the remainder of the scheme, which would comprise nearly the whole of the administrative portions, including operation rooms and isolation wards, all of which are urgently needed.

Medical Societies.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

Congenital Hypertrophic Stenosis of the Pylorus.

A MEETING of this society was held on Nov. 8th, the President, Mr. BRYANT, being in the chair.

Dr. EDMUND CAUTLEY read a paper on Congenital Hypertrophic Stenosis of the Pylorus. The condition illustrated by the cases described was one in which the pylorus of the infant was found post mortem to be represented by a well-defined, cylindrical, thick-walled tube, with its lumen exceedingly small or completely occluded. The affection was of importance in its immediate effect on the life of the infant, and probably also in its relationship, when present in a modified form, to the hypertrophic stenosis of the pylorus in adults. The first case of the kind was recorded in 1841, and a search into the literature of the subject yielded, with those reported by Dr. Cautley, a total of 20 undoubted instances of the condition. Reference was also made to some less marked cases, some in patients examined post mortem and others in patients who presented characteristic symptoms and yet recovered. One of the cases under Dr. Cautley's observation was that of a male infant who died in the fifteenth week of life from vomiting and marasmus. There was apparently no inherited taint and nothing in the condition of the child at birth to indicate disease. Constipation was present from birth and vomiting began at the age of three weeks and persisted. Another abnormality was present—viz., a large cavity in the right hemisphere of the brain. The second case was that of a male infant who died in the eighth week of life "in a fit." Vomiting had commenced a few days after birth and the child rapidly wasted. The following were regarded as characteristic features of the disease: (1) vomiting, occurring without apparent cause and persisting in spite of treatment; (2) the absence of bile from the vomited matter; (3) obstinate constipation; (4) marasmus; (5) the presence of a tumour in the region of the pylorus; (6) the absence of abdominal distension except from dilatation of the stomach itself in some instances; and (7) the absence of signs or symptoms of gastritis and of the more common forms of intestinal obstruction. The influence of inherited disease, family predisposition, and sex were apparently unimportant. The child had usually been noted "a fine baby born." Symptoms might occur within a few days of birth or later in life, but almost invariably within the first month. The pathological changes were illustrated by specimens. In each case the pylorus was about an inch long, forming a firm, thick, elongated tumour, well defined at either end, and of about the size of the last joint of the little finger. The thickening was clearly seen to be due to a relatively immense hypertrophy of the unstriped circular muscle-fibres forming the middle coat of the pylorus. The other changes which might be present in the pylorus, stomach, and œsophagus were secondary to the stenosis produced by the contraction of this hypertrophied muscle. Thus the mucous membrane was thrown into longitudinal folds and appeared to be thickened, but microscopical examination showed that there was no actual thickening of this layer. It was due to the contraction and was an important factor in the production of the stenosis, blocking up the already narrowed lumen. The stomach and œsophagus might be dilated, and the former might present signs of secondary gastric catarrh. Diagnosis depended entirely on the characteristic symptoms arising during the first few weeks of life and the presence of a tumour. The tumour had been noted in two cases during life. Treatment must be merely palliative unless the presence of the tumour could be demonstrated. In such a case Dr. Cautley suggested surgical measures as offering the best prospect of cure. No explanation was given of the cause of the condition, but it was suggested that it might result from a redundancy of fœtal growth, due to the anxiety of nature to provide an efficient pyloric sphincter.

Dr. NORMAN MOORE referred to the point mentioned by Dr. Cautley, that the hypertrophy was sharply limited to the pylorus, and said that it was of interest in connexion with the similar limitation observed in specimens of epithelioma of the pylorus which rarely if ever extended down into the duodenum. He thought that this suggested that the pylorus was the point of junction of the two processes from which the alimentary canal was developed.

Dr. H. D. ROLLESTON said that since Dr. Cautley had written his paper he himself had recorded a similar case, in which, however, no tumour could be detected during life, and Dr. Metzler had also published several cases this year in America. The most interesting question was in connexion with the causation. It was difficult to put aside the theory of Dr. John Thomson of Edinburgh that the condition was due to spasm. Dr. Thomson suggested that it might be due to the fœtus absorbing amniotic fluid, which in these instances acted as an irritant and so set up the spasm. Dr. Metzler, however, in opposition to this view, maintained that there was no proof that spasm of the pylorus gave rise to hypertrophy. Dr. Rolleston thought that the change was confined to the muscular coat, and that any change in the submucous coat was due to compression, and that any thickening of the mucous membrane was of a catarrhal character, secondary to the spasm. He referred to a specimen of similar hypertrophy of the œsophagus occurring without known cause in a man, aged fifty-four years, which he showed at a recent meeting of the Pathological Society.[1]

OBSTETRICAL SOCIETY OF LONDON.

Tubo-Abdominal and Tubal Pregnancy.—Exhibition of Specimens.

A MEETING of the society was held at 20, Hanover-square, W., on Nov. 2nd, Dr. C. J. CULLINGWORTH, President, being in the chair.

Mr. BLAND SUTTON read two papers on Tubal Pregnancy. The first paper consisted of the record of a case of tubo-abdominal pregnancy in which a woman, twenty-four years of age, conceived in her left Fallopian tube, and the pregnancy went to term. The fœtus escaped from the amnion, and at the operation was alive and among the intestines, merely tethered by the umbilical cord. The placenta was removed without difficulty and with a very trifling loss of blood. The mother recovered but the child only survived extraction three hours. The second paper consisted of criticisms and deductions based on a report of a specimen presented to the society by Mr. Alban Doran in May, 1898, described as Hæmorrhage from the Fallopian Tube without Evidence of Tubal Pregnancy. Mr. Sutton's object was to prove that the specimen was an excellent example of "complete tubal abortion." This contention was supported by a re-examination of the specimen and illustrated by additional cases. Criticism was also extended to some other records recently published in the society's Transactions.

Mr. ALBAN DORAN wished it to be remembered that his communication was designedly entitled "Hæmorrhage from the Fallopian Tube *without Evidence* of Tubal Gestation," and not "*independent* of tubal gestation." In his paper he further declared: "I am very suspicious of alleged cases of hæmorrhage from the tube into the peritoneum not due to tubal gestation." He would have been much interested to see a demonstration of chorionic villi found in the clot in his specimen, but Mr. Sutton and Mr. Shattock had failed to find any. Walther had also uttered a warning against taking almost structureless fibrinous deposits for villi. There was no reason why clots from the tube not associated with tubal gestation and abortion should not be smooth and elliptical. As chorionic villi had not been found the case, in his opinion, remained not proven.

Dr. MCCANN said that the case which was the subject of discussion came under his care. The patient had suffered for some weeks from constant and copious discharge of bright red blood which in his experience was quite exceptional. In another case the dilated tube contained an ovoid blood-clot with a small central cavity. A careful examination of the clot and the tubal wall failed to detect chorionic villi. This case was probably one of hæmato-salpinx not caused by tubal pregnancy.

Dr. EDEN said that a good deal of care was necessary in

[1] THE LANCET, Nov. 5th, 1898.

Digitized by Google

examining masses of blood-clot for chorionic villi. He had known fibrin rings and sections of the tubal plicæ exhibited as chorionic villi. If a careful search had been made, in Mr. Doran's opinion, and no villi were found he thought it pretty certain that it was not a mole.

Dr. AMAND ROUTH said that Mr. Bland Sutton's paper had brought out clearly the fact that after tubal rupture the Fallopian tube might recover itself and look normal in a few days, and after tubal abortion had been proved to have resumed its normal size and appearance even in a few hours.

The PRESIDENT was glad that Mr. Sutton had called attention to the question as to what happened in cases of pelvic hæmatocele from incomplete tubal abortion where the tubal mole remained in the tube after the hæmatocele had undergone absorption. It was a question on which more light was needed. He himself was disposed to agree with Mr. Sutton that an unremoved or unexpelled tubal mole was apt to cause trouble and he was not sure that it was not a source of serious danger to the patient. He had seen a case in which the mole-containing tube had become twisted on its axis, with results similar to those which occur when the pedicle of a small ovarian cyst becomes twisted. He had also seen a case where there was reason to believe that the mole had become septic and set up peritonitis.

Mr. BLAND SUTTON, in reply, contended that it was idle to deny that the clot in question was the product of tubal pregnancy. A tubal mole with such definite characters indicated that it was the result of tubal pregnancy as clearly as a potato was known to be the product of Solanum tuberosum. The difficulty of detecting the villi was probably due to the fact that the mole had been extruded from the tube many weeks. In reply to Mr. Targett he observed that in some cases of tubal abortion villi were demonstrable in the tube; in other cases the tubal mucous membrane was quite smooth.

The following specimens were exhibited:—

Mr. ALBAN DORAN: (1) Fibroma of the Broad Ligament, weighing 44 lb. 8 oz., successfully removed from a woman aged twenty-eight years; and (2) Sarcoma of both Ovaries.

Dr. TATE: Sloughing Fibro-myoma of the Uterus occurring twenty years after the Menopause.

Mr. BUTLER-SMYTHE: A Microscopic Section of Chorionic Villi from a Case of Tubal Gestation.

Dr. AMAND ROUTH: Uterine Appendages showing Hæmato-salpinx.

The PRESIDENT: Œdematous Subperitoneal Fibro-myoma removed by Hysterectomy.

HARVEIAN SOCIETY OF LONDON.

Malignant Disease of the Large Bowel.—Typhoid Fever.

A MEETING of this society was held on Nov. 3rd, the President, Dr. J. F. GOODHART, being in the chair.

Mr. W. H. BATTLE read notes of three cases of Malignant Disease of the Large Bowel, in each of which he had been called upon to operate for intestinal obstruction; in two cases the growth was removed at a subsequent operation, in one case it was excised at the time. They had been recently operated on at St. Thomas's Hospital, and one still remains under treatment. The result in each had been satisfactory. Case 1, a very rare one, was that of a man, aged forty-four years, who had a history of stoppage of the bowels three years previously, but he had apparently recovered from that attack and was well until three months before admission, when he suddenly became bad again, with increasing abdominal distension, pain, and the passage of a good deal of blood from the rectum, but no vomiting. Growth could be felt in the rectum. This proved to be an intussusception with the growth in the intussusceptum near the apex. Right iliac colotomy gave relief. Some weeks later the apex of the intussusceptum and the growth were excised through the rectum. Finally, the artificial anus was closed and although this was not completely successful the man was rendered so much more comfortable that he refused further relief. Case 2 was that of a woman, aged twenty-nine years, who had been seen by the President the day before Mr. Battle operated for the first time. She had all the signs of intestinal obstruction of chronic character and the diagnosis of malignant growth of the large intestine, either descending colon or sigmoid flexure, was made. Exploration was carried out and showed a hard growth of moderate size in the splenic region. An artificial anus was made in the left linea semilunaris below the ribs as it was hoped that at a subsequent operation, when the woman was in a better state, it might be possible to excise the growth and the artificial anus at the same time. The first operation was done on August 24th and after admission to St. Thomas's Hospital the second operation was performed on Sept. 23rd. The artificial anus and the growth were excised, the ends of the bowel were closed, and a lateral anastomosis by suturing was effected with the best results. The patient was able to leave for her home about three weeks afterwards in a very satisfactory condition. Case 3 was that of a woman, aged forty-five years, who was admitted to St. Thomas's Hospital on August 4th with intestinal obstruction of a fortnight's duration. She had had much vomiting, abdominal pain, and increasing distension of the abdomen. A median incision showed the cause of the obstruction to be a cancerous stricture of the sigmoid flexure. A second incision in the left iliac region was well over the seat of the disease, and as the patient's condition was fair and the growth could be brought up it was excised by the method recommended by Paul and a tube placed in each of the divided ends of the gut. The two ends and the mesentery were sutured together side by side and brought outside with the tubes. A few stitches secured them to the abdominal wall. The obstruction was completely relieved and the patient was now undergoing treatment for the re-establishment of the intestinal canal, the septum being divided gradually by the application of clamp forceps. Her general state of health has much improved. In none of these cases was there apparent glandular disease. Mr. Battle dealt upon the advisability of treating similar cases before obstruction had set in and the patient's state had become much more serious. He considered that the operation of colotomy should be rendered much less frequent by an early removal of the growth when diagnosis had been made. The advantages of "short-circuiting" and lateral anastomosis were pointed out and he expressed himself as against the use of mechanical contrivances.—The PRESIDENT alluded to a case of chronic intestinal obstruction caused by a mass of new growth in the neighbourhood of the splenic flexure. The bowel was "short-circuited" by means of Murphy's tube. The symptoms were completely relieved by the operation and the patient had remained well ever since.

Dr. SIDNEY PHILLIPS read a paper on the Treatment of Typhoid Fever. He referred to the changes which occurred in typhoid fever, amounting in time to a change of type. This was seen in the lessened severity of abdominal symptoms of late years. Thus, while Murchison estimated diarrhœa in 1862 as occurring in 96 of 100 cases it occurred now in not more than about half. The lessened severity of abdominal symptoms corresponded with probably less severe ulceration and of late a good number of necropsies of typhoid fever cases without ulceration had been recorded. It appeared that local lesions specific to typhoid fever and intercurrent affections such as pneumonia could not account together for more than 5 of each 100 deaths, and the remaining 50 per cent. or more were due to toxæmia, pyrexia, heart failure, or asthenia. It was necessary in treatment to keep up failing heart power by tonics and food, but heart muscle weakened by disease failed to respond well to cardiac tonics. Diffussible stimulants were useful. Diarrhœa should be checked by enemas rather than by drugs given by the mouth. Hæmorrhage was often controlled by hamamelis. The chances of recovery from perforation were so remote that operation offered the best chance, but the difficulty in many cases was the diagnosis of perforation.—Mr. HAZEL asked for further information as to the indications for the use of stimulants in typhoid fever.—Dr. WILSON inquired as to the exact time after cessation of the fever when it might be considered safe to give solid food.—Mr. EASTES fully agreed with Dr. Phillips as to the uselessness of phenacetin, antipyrin, and similar drugs; any lowering of temperature which they produced passed quickly away and was followed by increased general depression. He did not employ cold baths, but always ordered wet pack (with or without ice).—Dr. JOHN BROADBENT thought that the cold bath treatment ought to be more generally adopted in this country, as its routine employment in America and on the continent had indisputably diminished the percentage of fatal cases.—Dr. H. A.

Digitized by Google

CALEY advocated increased attention to systematic hydrotherapeutic measures, adapted according to the nature and circumstances of individual cases, and confirmed what had been said as to the value of hamamelis in the treatment of intestinal hæmorrhage.—Dr. OWEN FOWLER gave his personal experience of the cold-bath treatment and pointed out the comfort experienced after the bath, the change from restlessness and fever to calm and rest.

BRADFORD MEDICO-CHIRURGICAL SOCIETY.

The Life and Times of John Milligan.—Strangulated Hernia.—Exhibition of Cases and Specimens.

A MEETING of this society was held at the Royal Infirmary, Bradford, on Oct. 25th, the President, Dr. BERRY, being in the chair.

The PRESIDENT gave his opening address on the Life and Times of John Milligan, surgeon, of Keighley, 1812–1876. He was born at Crosshills in 1812 and was apprenticed to a Keighley surgeon. He subsequently entered as a student at University College and Middlesex Hospitals and obtained the Licence of the Apothecaries' Society in 1834. He then returned to his native district and commenced practice. He was extremely industrious, beginning work at 5 o'clock in the morning and doing much of his work on foot—he often walked from 15 to 20 miles a day. In 1838 he was appointed first medical officer of the Keighley Union and public vaccinator. Mr. Milligan was an enthusiastic supporter of the Mechanics' Institute and frequently lectured there. He read widely in preparation for these lectures and paid much attention to works bearing on sociology and sanitation. Though he was much respected for his earnestness and enthusiasm for the public welfare in social and sanitary matters he was hindered in his work by popular ignorance and prejudice. His denunciations of the overwork and under-pay of the people and of the miserable hovels in which they lived doubtless often earned for him the dislike and opposition of employers and owners of property. In 1855 Mr. Milligan was appointed medical officer of health. By one who knew him intimately he was described as much in advance of his time in all sanitary matters and that he was much vexed by the popular indifference to such subjects. Among papers contributed by him to both the London and provincial press was one on the Prevention of Accidents in Mines, on Vagrancy and Crime, on Common Lodging-houses, and on Hospitals and Dispensaries. In 1849 he won the Fothergillian gold medal with an essay on the Influence of Civilisation on Health and Disease. In 1857 Mr. Milligan read a paper before the British Association at Dublin on a New Method of preserving Vaccine Lymph in Glycerine and on an Instrument for facilitating Vaccination. The method was to soak dried vaccine crusts in glycerine for six months and he apparently obtained results identical with those of arm-to-arm vaccination. Mr. Milligan was dexterous and successful as an operating surgeon under very unfavourable conditions, both as regards the patient's surroundings and also the lack of skilled assistance. He introduced the use of chloroform into Keighley, having first tried the effect upon himself. Apart from his professional work he interested himself deeply in local politics and tried to further the cause he thought worthy of support by both tongue and pen. He was much attached to the study of natural history in all its branches and was an authority on the local fauna and flora. He retired from active practice in 1866, retaining only his public health appointment until his death ten years later at the age of sixty-five years. A point of considerable interest was brought out by the lecturer in connexion with the attitude of the Keighley people to vaccination, Keighley now having one of the lowest vaccination rates in the country. In 1853 vaccination was made compulsory in England. Previously to this time Mr. Milligan was allowed to vaccinate at any time and on any day at his surgery or at the patient's houses, but most of the vaccinations were as a matter of fact performed during the warmer months of the year. The people were so alive to the value of the protection they gained from it that in outlying districts where medical men rarely went old women often performed the operation with a needle. The only anxiety felt was as to the source of the lymph, and so long as people were allowed to select this they raised no objection to the operation. When vaccination became compulsory and it was necessary to bring children at certain hours to a particular place then troubles commenced. Sometimes stations were a long way off and to reach them involved exposure in all kinds of weather, and this was felt to be intolerable for both mother and child. When the people found that by electing as guardians only such as would not enforce the compulsory clauses of the Act they could escape with impunity they were not slow to avail themselves of their privileges in this direction.—A vote of thanks to the President for his address was proposed by Dr. W. A. EVANS, seconded by Dr. RABAGLIATI, and carried unanimously.

Dr. ALTHORP related two cases of Strangulated Hernia exhibiting somewhat unusual features. The first case was that of a woman, sixty-six years of age, who for many years had had double femoral hernia, the left being irreducible for a considerable time. She was admitted to hospital with symptoms of obstruction and the vomiting was stercoraceous. The hernial sac of the left side was exposed and a pronounced gangrenous odour was at once perceived. On opening the sac it was found to contain a loop of large intestine about 8 in. long which was quite gangrenous. There did not seem to be any tight constriction at the femoral ring and the gangrenous bowel extended rather above this point. The wound was enlarged upwards through the femoral opening, the gangrenous bowel was cut away, and a large rubber tube was fixed into each cut end, the wound being left open. No fæcal discharge occurred through either tube and as the symptoms persisted the hernia on the right side was opened up after two days. A small piece of omentum, which was irreducible, was found in the sac and was removed. The symptoms persisted and the patient died two days after the second operation. A complete post-mortem examination was not allowed, but examination through the operation wound showed that there was a volvulus of the sigmoid flexure which had descended into the hernial sac and the descending colon was filled with hard fæces. The second case was that of a man, forty years of age, with a strangulated left inguinal hernia. Herniotomy was performed and there were found two sacs, one within the other, the inner containing omentum and bowel. Dr. Althorp described the condition as one of congenital inguinal hernia with a patent funicular process.

Dr. JAMES KERR showed two patients, mother and son, who each presented peculiar symptoms apparently as Sequelæ of Influenza. The mother, forty-seven years of age, together with the rest of the family, suffered from a febrile illness seven years ago, from which all the members except the mother and son recovered completely. In the case of the woman recovery from the influenza was much delayed, and at the end of two years she noticed failure of vision, the left eye being affected first and then the right. Three years ago the gait became weaker, unsteady, and reeling, and now the patient could not walk a few yards without great exhaustion. The affection of locomotion was ushered in by numbness of the feet and a sensation of walking on wool. There was no tremor of the hands and no wasting. Mentally she was quite clear, but rather emotional (inclined to tears). Sight was very bad—fingers were counted at a yard; faces were fairly well recognised, also colours. There was occasional (doubtful) nystagmus. The ocular movements were good; the pupils reacted sluggishly. Optic nerve atrophy was present on both sides. Taste and smell and sensibility were natural. Hearing was rather dull. The knee-jerks were exaggerated and ankle clonus was present. She could not stand without assistance. The gait was spastic and incoördinate. There was incontinence of urine and cystitis. The son, twenty-five years of age, had good health till he had influenza seven years ago. As in the case of the mother there was prolonged convalescence followed by failure of sight and power of walking. During the past year he had had difficulty in micturition. Mentally he was quite bright, but inclined to be emotional. Sight was bad; he counted fingers at a yard. He could not distinguish faces; colours were recognised. The pupils were dilated and reacted slightly to light. There was slight nystagmus on moving the eyes. The arms were muscular and slightly incoördinate. The legs were incoördinate; the knee-jerks were exaggerated; there was no ankle clonus. Sensibility was natural. Dr. Kerr remarked that there was a disseminated lesion affecting the central nervous system, probably toxic in origin. He stated that the commonest cause was syphilis but that similar cases had been described as following the specific fevers. The fact that both mother

Digitized by Google

and son were attacked showed a family susceptibility to this particular poison.

Dr. KERR also showed a girl, aged ten years, who had suffered from the disease called by Charcot Astasia Abasia. The symptoms came on after influenza. There was at first some difficulty in walking which culminated in complete inability to either stand or walk. She was treated by suggestion and in three days could walk well. There had been slight return of the symptoms consequent on over-exertion.

Dr. EURICH gave a Microscopical Demonstration.

Dr. GLADSTONE showed a number of Pathological Specimens including the Œsophagus of a child in which a halfpenny had been impacted for ten months. There had been a lateral pouch formed at the seat of obstruction.

SHEFFIELD MEDICO-CHIRURGICAL SOCIETY.

Exhibition of Cases and Specimens.

A MEETING of this society was held on Oct. 27th, the President, Dr. ALFRED ROBINSON (Rotherham), being in the chair.

Mr. SIMEON SNELL introduced: 1. Three instances of Entropion which had been treated by eschar by caustic potash (Theobald's method). The result in each case was excellent. 2. Three cases of Ectropion—(1) severe of the upper eyelid treated by division of subcutaneous bands and temporary union of the eyelids; (2) of the lower eyelid treated by raising a V-shaped flap and temporary union of the eyelids; and (3) from granular lids, treated by shortening the palpebral fissure and at the same time inverting the lower eyelid.

Mr. SNELL also related particulars of a case of Diphtheritic Conjunctivitis in a woman in which the bacillus of diphtheria had been discovered. Complete recovery resulted. He referred, also, to a case in an infant treated by antitoxin and to another in an elderly woman with well-marked membrane. In the latter the bacillus was not to be found; in the former the result of the bacteriological examination was not recorded.

Mr. PYE-SMITH showed a man on whom he had performed Colotomy by the method recently described by Mr. F. T. Paul as based on the principle introduced by Hahn in the performance of gastrostomy. It was easy and rapid in performance and had given a very good result. The patient was wearing a truss as recommended by Mr. Paul.

Mr. PYE-SMITH also showed a girl, aged eleven years, with Congenital Displacement of the Left Hip. There was 2in. of shortening which could be reduced by half by traction, but she could walk and run well with a raised boot. A skiagraph showed that the head and neck of the femur were not much abnormal as regards size and direction.

Mr. ARCHIBALD CUFF showed and described a case of Double Congenital Dislocation of the Hip.

Dr. PORTER showed: (1) A case of Insular Sclerosis; (2) a case of Locomotor Ataxia in a woman; and (3) a case of Incipient Progressive Muscular Atrophy (?).

Mr. PRIESTLEY showed a case of Leontiasis Ossea.

Dr. WILKINSON showed a specimen of Ruptured Tubal Mole obtained by operation from a woman, aged thirty years. The patient had had three children, the last nine years ago. She missed two periods and a week later began "flooding." She had sudden severe pain in the lower abdomen a week later. Since that time up to the day of admission (four weeks) she suffered from intermittent hæmorrhage from the uterus and abdominal pain. A tumour was detected by vaginal examination to the left of the uterus, feeling like a distended tube. The sound passed 3 in. The abdomen was opened and many clots and blood-stained serum were found in the peritoneal cavity. The left uterine appendages were removed. They were found to consist of a distended Fallopian tube which had ruptured. Through a rent a mole protruded which was still attached to the distended tube in the unruptured portion. The patient made a good recovery. Dr. Wilkinson drew attention to the method of incising the abdomen by "going round" the rectus, which he thought was applicable at the inner as well as at the outer border of the muscle.

Mr. SIMON RYAN showed a very large Gall-stone removed from a patient under his care, a man sixty-three years of age, by Dr. Sinclair White.

Dr. SINCLAIR WHITE exhibited and made remarks on Renal Calculi (three cases) and skiagraphs of Old Dislocation of the Shoulder and Renal Calculus.

The PRESIDENT, Mr. PYE-SMITH, Dr. SINCLAIR WHITE, Mr. ARCHIBALD CUFF, Dr. ARTHUR HALL, Dr. GODFREY CARTER, Dr. A. ANDERSON, Dr. ADDISON, and Mr. RICHARD FAVELL made remarks on the cases and specimens.

LIVERPOOL MEDICAL INSTITUTION.—A meeting of this society was held on Nov. 3rd, the President, Dr. Macfie Campbell, being in the chair.—Mr. Rushton Parker read notes of a case of a Large Gumma of the Liver which formed a prominent tumour. Exploration was undertaken and the greater part was removed.—Mr. F. T. Paul spoke.—Mr. Richard Williams showed a patient from whom he had scraped a well-marked Lupus from the Palpebral Conjunctiva of the Upper Eyelid.—Dr. Grossmann alluded to the rarity of the affection. The diagnosis might be confounded with syphilis, trachoma, and, in some countries, with leprosy. Trachoma was, however, mostly bilateral and there were no characteristic organisms present. He had recently examined 100 cases of trachoma without finding any. He was in favour of treating lupus by scraping or galvano-puncture. Possibly the x rays might prove of service.—Mr. Thelwall Thomas mentioned a case of Lupus of the Conjunctiva of both upper eyelids in a young man whom he had seen. He had a small patch of lupus at the tip of the nose and he had probably inoculated himself on the eyelids. Scraping and the rubbing in of iodoform were successful.—Mr. Rushton Parker and Mr. Shears made remarks.—Mr. Robert Jones showed a case of Osteomalacia in an unmarried girl, aged twenty years, one of four cases which he had seen. All the bones were softened, spontaneous fracture having occurred in the tibia. The bones of the left limb could be moved in any direction. The fingers were clubbed, the thickening being confined to the terminal phalangeal joints. The radiographs demonstrated immense thickening of the long bones, striation suggestive of the partial disappearance of lime salts, and crenated borders. Mr. Jones suggested feeding with bone-marrow and, should this fail, he would remove the ovaries.—Dr. T. R. Bradshaw was surprised to hear that Mr. Jones had seen so many cases, the disease being so rare. Late rickets and cancerous infiltration of bones had sometimes been included in the records of cases of osteomalacia. Most important of all was the condition described as multiple myeloma, which was associated with great quantities of a kind of albumose in the urine. Dr. Bradshaw maintained that it was impossible to be sure of the true nature of the case exhibited without a careful investigation of the urine.—Mr. Clemmey spoke.—Mr. Hugh E. Jones read a paper on the Importance of the Early Detection and Treatment of Suppuration in the Tympanic Cavity and Mastoid resulting from Otitis Media. The mortality in complicated chronic suppurative otitis was still high in spite of the great progress made in operative treatment in recent years. The after history of successful cases was not always quite satisfactory. The radical tympano-mastoid operations, though of immense importance in the treatment of chronic cases, did not restore the ear to anything like its normal condition. With the exception of primary tubercle all the chronic cases began as acute ones; it was therefore highly necessary to thoroughly deal with acute cases. He described the course of acute otitis media and indicated the cases which required (1) paracentesis of the membrane, (2) exploration of the mastoid cells, and (3) opening of the mastoid antrum. The operations required at this stage were simple, easy of performance, and with ordinary skill perfectly safe.—Dr. Permewan agreed as to the advisability of early operation in acute cases. The real difficulty was in diagnosing mastoid complication; some cases of otitis externa and of tympanic inflammation alone closely simulated mastoid disease. Still, the only way to prevent acute cases becoming chronic was to operate early.—Mr. Robert Jones related four cases where he had opened up the lateral sinus and cleared the internal jugular vein. Two recovered.—Mr. W. M. Banks, Mr. Paul, Mr. Parker, Mr. Shears, Mr. Richard Williams, and Dr. Alexander spoke.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.—An ordinary meeting of this society was held in the society's rooms at the West London Hospital on Nov. 4th, Dr. S. D. Clippingdale, President, being in the chair.—Dr. F. J. McCann read a paper on Cases illustrating Difficulties in the Diagnosis of Early Tubal Pregnancy. Three cases were described in detail and remarks were made on the differential diagnosis of early tubal pregnancy. Case 1.—The patient was a woman, aged twenty-seven years; she had been married three years and was sterile. Three weeks before she was seen she had an attack of pain in the left iliac region, accompanied by sickness and faintness. At that time she had missed her monthly period for fourteen days. On bimanual examination an elongated fluctuating swelling was felt to the left of the uterus. As the contents of this swelling were evidently leaking into the abdominal cavity an abdominal section was performed. The abdominal mass proved to be a dilated tube containing an ovoid clot with a small central cavity. No evidence of chorionic villi could be found. The patient recovered. Case 2.—The patient was a married woman, aged thirty-seven years; she had had four children, the youngest being two years old. After a period of three months' amenorrhœa she was suddenly attacked with pain in the right groin and thigh. The temperature varied between 101° and 104° F. The patient was very blanched and collapsed. The abdomen was distended and very tender. An elongated swelling was felt in the right posterior quarter of the pelvis. Abdominal section was performed and about a pint of blood-clot was found in the abdominal cavity. The swelling was a well-marked example of a tubal mole. The patient recovered. Attention was directed to the difficulties in the diagnosis of early tubal pregnancy. Other cases were mentioned. The significance of elevated temperature, irregular uterine hæmorrhages, passage of decidual membranes, and amenorrhœa were discussed. The last case described in detail exhibited many of the signs and symptoms of tubal pregnancy. At the operation, however, a dermoid cyst with a twisted pedicle was removed.—The paper was discussed by Dr. Alderson, Dr. Addinsell, Dr. Campbell Pope, Dr. Drummond Robinson, Mr. Atkinson, and Mr. Twynam, and Dr. McCann replied.—Dr. Addinsell then read a paper on Ovariotomy followed by Parotitis. The patient was an unmarried woman, aged thirty-five years, from whom, in October, 1897, he removed a large multilocular ovarian cyst. There was a history of a severe sudden illness 5 months prior to the operation and lasting 6 weeks. There was found to be a twisted pedicle and the cyst was adherent to the bladder and uterus. The patient did well for 7 days. On the morning of the eighth day there was swelling of the left parotid gland. The temperature was 103° F., there was dryness of the mouth, and the submaxillary gland was involved. Suppuration did not occur and the patient left the nursing home at the end of three weeks. The origin of parotitis following abdominal operations was discussed, and it was pointed out that the cases collected by Mr. Stephen Paget in 1886 if carefully examined all pointed to a septic origin. Dr. Addinsell admitted the part played by the large network of sympathetic nerves in the abdominal and pelvic viscera, but he held that the lymphatic system must also take its share of responsibility. He thought that the cases relied on by Mr. Stephen Paget for establishing the theory of nervous origin were in reality cases of septic infection, and he considered that the whole weight of evidence was in favour of parotitis following operation being due to a mild form of sepsis.—The paper was discussed by Dr. McCann, Dr. Percival White, Dr. Gibbes, Mr. Stephen Paget, Mr. Bidwell and Mr. Keetley, and Dr. Addinsell replied.

BEDFORD MEDICAL SOCIETY.—A meeting of this society was held on Oct. 27th, the President, Mr. M. F. Cock, being in the chair.—Dr. G. P. Goldsmith opened a discussion on Diphtheria. He related his early experiences in 1859; next in 1863, when he had about 50 cases, and little children perished in large numbers at the end of a week or ten days from heart failure. He noted the great change for the better produced by the introduction of serum injections and pointed out the importance of early treatment. In about 20 cases recently under his care, all of which recovered, the serum was only used in the severe cases. In addition to the serum the throats were painted with a 1 in 1000 solution of perchloride of mercury and sprayed with sulphite of soda. He quoted statistics from 53 hospitals in which 7277 cases were treated with serum injections, with a mortality of 20 per cent., against a previous mortality of 44 per cent.—Mr. G. Robinson related a mild case in the swabbings from which no bacilli were found, but paralysis afterwards occurred.—Mr. Nash said that he and his partner had treated 50 cases since 1892 with 1 death. In 29 out of the last 32 cases bacilli had been found; in 25 cases serum injections were used, the number varying from 1 to 7 per head. Paralysis had occurred in 6 cases, 3 of which were treated with serum; one of these, which had 3 injections, died. Between June 29th and July 19th of this year he had seen 13 cases, all of which drank unboiled milk from the same dairy. Six other cases were heard of in the same period drinking the same milk and two or three cases which did not drink this milk. The latter were probably the ordinary sporadic cases.—Mr. A. Sharpin and Mr. T. J. Tonkin contested the milk origin of this epidemic.—Dr. F. B. W. Phillips related a puzzling case of Pustular Eruption on the hands of a child.—Dr. S. J. Ross, referring to Diabetic Urine, stated (1) that the appearance of albumin *per se* does not materially affect the prognosis; (2) the presence of diacetic acid and acetone does; and (3) he had noticed fatty casts in the urine appearing from 24 to 72 hours before the onset of coma.—Mr. Nash read notes of a case of Labour obstructed by an Ovarian Cyst in the Pelvis. The membranes had ruptured and the cord was prolapsed. The latter was replaced, the cyst was aspirated, and the child was delivered with forceps. The patient made an uneventful recovery.—Mr. Nash showed Congenital Cystic Kidneys from a child, aged six months. The colon was also malformed.—Mr. Nash also showed a Spindle-celled Cystic Sarcoma of the Gracilis and Adductor Longus removed from a man, aged sixty-eight years. The lump was first noticed by the patient eighteen months ago. In June of this year it was first seen by Mr. Kinsey and taken for a hæmatoma in the gracilis. It was incised by Mr. Kinsey and a large cyst was evacuated of its contained blood. It soon healed, but as it continued to enlarge was removed with much of the involved muscles. This patient's wife died in May, 1897, aged sixty years, from a malignant tumour of the sigmoid flexure.

NOTTINGHAM MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on Nov. 2nd, the President, Mr. T. Davies Pryce, being in the chair. The President delivered an address on Limitations in Medicine. He remarked that our limitations are many and meet us in every field of medicine, arising as the result of our restricted mental capacity, for the accepted doctrine of to-day is frequently the demonstrated error of to-morrow, from an overweening confidence in our knowledge causing us to accept a few facts as the whole truth and from a mental tendency to think in certain grooves. Often the brilliancy of some new discovery blinds us to the darkness of our knowledge, and thus we think the final goal has been reached while it merely marks a stage upon the road. What, he said, is known of the true nature of carcinoma, of hysteria, and melancholia? The frequent failure of past theories should ensure caution in accepting new views and practices. The "classification" of disease is necessary, but is often a hindrance, and none of the groups should be looked upon as final; phthisis and certain forms of pneumonia afford examples of recent emancipation from old forms of classification and are an instance of how a group of facts if taken alone may bear one interpretation, but which, if viewed by the light of further discovery, must necessarily be looked upon from a new standpoint and in consequence require a new interpretation. As an instance of how, by allowing our minds to think in a groove, we are apt to permit one important fact to obscure others of possibly equal value Mr. Pryce alluded to the acceptance of the water-borne infection of typhoid fever, and showed that many other possible sources of infection were thus disregarded. Another cause tending to confine and retard progress is a too ready assumption of knowledge which we do not possess, and the habit of taking refuge in expressions, the substitution of mere words for a definite explanation of observations, such as the terms "diathesis," "immunity," "predisposition," and the like.—A hearty vote of thanks was accorded to the President on the proposition of Dr. Cattle, seconded by Mr. Powell.

ÆSCULAPIAN SOCIETY OF LONDON.—A meeting of this society was held on Nov. 4th, the President, Mr. D. H. Goodsall, being in the chair.—The President

Digitized by Google

showed two boys, aged five years, treated by the American Stirrup Weight Extension and lateral sandbags with a sheet over the limb for Femoral Fracture in the Mid-third. One of these raised his injured limb from the bed on the seventeenth day.—Dr. R. Ostlere showed a man, aged forty years, the subject of Chronic Glossitis of three years' standing, whose tongue had three ulcers of from 1 cm. to 3 cm. in diameter, with thickened, irregular edges and in part a sloughy base. The right half of the tongue was very markedly swollen. The patient had had various treatment, but had benefited by none except silver nitrate locally. There was no history of syphilis.—Dr. Leslie Durno showed a man, aged thirty years, a coach painter, the subject of Extensor and Interossei Palsy coming on eighteen months after the first of a series of eight attacks of colic due to lead. The sulphide line on the margins of the gum was well marked. There was no sensory symptom. The left hand was attacked two months after the right.—Mr. W. Campbell M'Donnell showed a man, aged twenty-eight years, the subject of Recurrent Rectal Carcinoma, for whom excision of the rectum was done thirteen months before. Recurrence was in the deep parts as well as the skin.—Dr. B. G. Morison showed a woman, aged twenty years, whose right first, second, and third Nails becoming longitudinally ridged separated from the nail-bed and were shed close up to the lunula. She was also the subject of brachial neuralgia. He thought the condition a tropho-neurosis.—Dr. E. F. Willoughby showed a specimen of False Membranes from a case of Mucous Colitis in a man, aged seventy years, whose complaint commenced in April, 1898, and, with relapses, went on till the end of October. Under the microscope the membrane showed no structure but mucous cells.

MANCHESTER MEDICAL SOCIETY.—A meeting of this society was held on Nov. 2nd, Mr. G. A. Wright, President, being in the chair. — Mr. Southam made some remarks, which will be found in another column, on Amputation for Charcot's Joint Disease and mentioned four cases where the leg had been removed below the knee for disease of the ankle or tarsal joints. In each instance the wound healed quickly without suppuration, a useful stump resulting. The patients, who were males between forty and fifty years of age, presented other well-marked symptoms of locomotor ataxy.—Dr. Leech gave an account of the investigations made by pharmacists subsequently to the publication of the 1885 Pharmacopœia, which had showed that accurate dosage with the official preparations of belladonna and nux vomica was impossible, since however carefully such preparations were made their strength might vary widely owing to the difference in the amount of alkaloid contained in the crude drugs themselves. Hence the necessity for the changes made in the Pharmacopœia of 1898. He pointed out that the alkaloid contained in the maximum doses of the preparations of belladonna in the 1885 British Pharmacopœia varied from $\frac{1}{300}$th to $\frac{1}{75}$th of a grain. In the standardised preparation of the 1898 British Pharmacopœia the width of limit had been greatly lessened. The largest dose of the new tincture (15 minims) corresponded to $\frac{1}{180}$th gr. of alkaloids, the largest dose of the alcoholic extract to $\frac{1}{270}$th gr., these amounts being equivalent to about two-thirds and 1 drop of liquor atropinæ sulphatis respectively. The tincture and extract of nux vomica have been likewise rendered much less variable in strength than formerly by standardising according to the amount of strychnine instead of according to the amount of total alkaloid contained.—Dr. Ernest S. Reynolds made some remarks on the Uncertainty of Diagnosis of Cerebral Tumour and gave illustrative cases.

BRITISH BALNEOLOGICAL AND CLIMATOLOGICAL SOCIETY.—A general meeting of this society was held at 20, Hanover-square, W., on Oct. 31st, the President, Dr. W. V. Snow (Bournemouth), being in the chair. Dr. Snow referred to the loss sustained by the society by the death of Dr. Henry Lewis (Folkestone), who was the first President of the society.—The treasurer's report and balance-sheet were adopted after discussion by Mr. Blaker (Brighton) and Dr. Hyde (Buxton).—Dr. Snow then introduced the new President, Dr. Fortescue Fox (Strathpeffer Spa).—A vote of thanks to the retiring President was proposed by Dr. Symes Thompson, seconded by Dr. Ivor Murray (Scarborough), and carried. Dr. Snow replied.—A vote of thanks to the editor of the Journal was proposed by Dr. St. Clair Thomson, seconded by Dr. Gilbert (Tunbridge Wells), and carried. Dr. Hyde replied.—A vote of thanks to the treasurer and auditors was proposed and carried. Mr. Keetley, Mr. Ward-Humphreys, and Dr. Leonard Williams replied.—A vote of thanks to the council and secretaries was proposed by Dr. Younger, seconded by Dr. Gage Brown, and carried. Mr. Ward-Humphreys and Dr. Sunderland replied.—An ordinary meeting was then held, the President, Dr. Fortescue Fox, being in the chair. The President delivered an impressive address on the Province of the Spa Physician, which evoked great interest and attention.—Dr. Ewart proposed, and Mr. Bowen Davies (Llandrindod Wells) seconded, a vote of thanks to the President for his address and Dr. Fortescue Fox replied.

HUNTERIAN SOCIETY.—A meeting of this society was held on Oct. 26th when the following cases were exhibited:—Dr. F. J. Smith: An elderly man with supposed Bulbar Paralysis. He was admitted with inability to swallow, paralysis of the tongue, aphonia, and loss of palate reflex. The small arteries were extremely hard.—Dr. R. Hutchison thought that in the absence of muscular atrophy of the tongue the lesion must be above the bulbar nuclei, possibly in the lenticular nucleus or the inferior frontal convolution.—Dr. F. J. Smith: A boy, aged sixteen years, with Gangrene of the Left Foot and Mitral Regurgitation. He had recently suffered from pneumonia.—Dr. Sequeira: A case of Raynaud's Disease. The nose, ears, and nails were affected, but there had been no hæmoglobinuria.—Dr. Chaplin: A man, aged forty-two years, with a Thoracic Aneurysm. There was marked laryngeal stridor and the right pulse was much weakened, though the signs of disease were chiefly on the left side.—Dr. F J. Smith thought it might be due to atheroma of the aorta with dilatation and regurgitation.—Dr. A. T. Davies suggested that the sac had originated from the concavity of the aortic arch.—Dr. Sequeira: A child with supposed Cerebellar Tumour. He had a marked ataxic gait, double optic neuritis, and enlargement of the head.—Mr. Targett had seen a case with similar symptoms and diagnosed as cerebellar tumour which proved to be due to chronic hydrocephalus.—Dr. Kelson: Two cases of Congenital Syphilis.—Sir Hugh Beevor: Arthritis Deformans in an Elderly Man.

ROENTGEN SOCIETY.—The first annual meeting of this society was held on Nov. 1st at 11, Chandos-street, Cavendish-square, W. In the unavoidable absence of the President, Professor Silvanus Thompson, Mr. Thomas Moore took the chair. The report of the council was read and adopted. It showed a financial balance upon the year's proceedings of £46. Mr. C. W. Mansell Moullin was elected President for the coming year, 1898-1899. On taking the chair he gave a short address, in the course of which he insisted upon the need of a normal atlas of osteography and of collections of photographs illustrating special conditions. There were great possibilities for the future development of the new art in various technical directions. The annual conversazione will be held on Nov. 21st at the invitation of the new President. During the evening it was announced that a 10 in. coil had been presented to the society by Mr. Wilson Noble. The following is the list of officers:—President: Mr. C. W. Mansell Moullin. Past-President: Professor Silvanus Thompson. Vice-Presidents: Lord Blythswood, Professor Ferrier, Professor Gladstone, Dr. Macintyre, Mr. A. A. Campbell Swinton, and Dr Dawson Turner. Council: Mr. J. Mackenzie Davidson, Dr. F. E. Fenton, Mr. Greenhill, Dr. Hedley, Mr. Isenthal, Dr. F. H. Low, Mr. Wilson Noble, Mr. Sydney Rowland, Mr. Vezey, Mr. Snowden Ward, Mr. Webster, and Dr. Wolfenden. Hon. Treasurer: Mr. Thomas Moore. Hon. Secretary: Dr. Walsh, 5, Pump-court, Temple, E.C.

ILFORD MEDICAL SOCIETY.—At a general meeting of this society held on Nov. 3rd, the President, Mr. Best, in the chair, the subject of Affiliation with the Corporate and Medical Reform Association, Limited, was brought forward for re-consideration by means of a motion formally proposed by Dr. Griffith and seconded by Dr. Hanks, but unsupported, to rescind a resolution adopted on Oct. 6th to enter into affiliation. Whereupon the resolution of Oct. 6th, moved by Dr. Fraser, seconded by Mr. Houghton, was again put to the meeting and unanimously re-affirmed. At the previous meeting (Oct. 6th) a deputation was received

Digitized by Google

consisting of Mr. Murtaugh Houghton and Mr. R. B. Anderson submitting proposals of coöperation and affiliation in favour of corporate and medical reform, at which a resolution, moved from the chair and seconded by Dr. Duncan, approving of the policy and measures of the association, was carried *nem. con.*, and the resolution to enter into affiliation was, after a prolonged discussion, carried against three dissentients, who held that absent members should have a further opportunity of voting, for which purpose Dr. Griffith gave notice of his motion to rescind the resolution.—The Memorandum of Association was executed on Nov. 5th.

GLASGOW MEDICO-CHIRURGICAL SOCIETY.—This society held its third meeting on Nov. 4th, when Dr. Nicoll showed a case of Cerebellar Abscess successfully treated by operation.—Dr. Beatson then showed a Cystic Goitre removed by operation and also a large Fatty Tumour removed from the superior mediastinum. It lay beneath the deep cervical fascia and simulated a cyst protruding above the manubrium sterni.—Dr. James Adams and Dr. Nicoll each showed a specimen of large Meningo-encephalocele removed by operation, and Dr. Nicoll showed a Nævoid Tumour of the Intestine enclosed in a double intussusception involving over 5 ft. of bowel. It was successfully resected, having produced symptoms of acute intestinal obstruction.

ODONTOLOGICAL SOCIETY OF GREAT BRITAIN.—The first meeting of the new session was held on Nov. 7th at 40, Leicester-square, W.—The President, Mr. John Fairbank, delivered his inaugural address. After thanking the members for the honour which they had conferred upon him he referred to the prominent part which the society had played in the foundation of the L.D.S. diploma, and at the same time incidentally referred to the opposition which had been offered to this step by the Society of Surgeons practising Dentistry. He dwelt at some length on the bearing which the various portions of the curriculum have upon the practice of dental surgery, pointing out that in his opinion the mechanical portion of the training outweighed in importance the medical and surgical. In reference to the actual education of students he thought that only too frequently the pupil while serving his apprenticeship was neglected by the practitioner and left to the tender mercies of the workroom assistant. He considered, too, that the utmost possible supervision should be given to the student whilst acquiring his operative knowledge and he suggested that every student before being examined should present satisfactory evidence that he had performed in detail all the various operations which he was likely to meet with in the practice of his profession. Referring to the treatment of patients he thought there was much to be learnt and he in the course of his practice had come to the conclusion that firmness of purpose combined with patience and gentleness were required for successful treatment. He touched, too, upon, in his opinion, the advantage of the subdivision of dental surgery into specialities, but he did not think there was any chance of his ideas in that respect being realised.—Mr. C. E. Smith presented a communication on the Value of Tube Teeth in the Manufacture of Bridge-work.—Mr. Storer Bennett read an interesting paper on Ankylosis of Human Teeth to the Jaw. He narrated the details of four separate cases of this character which had come under his notice and in all four there was unmistakeable microscopical evidence of the tooth substance having become firmly blended with the osseous tissue. The subject had, in his opinion, an important bearing on the operations of replantation and transplantation of teeth.—In a discussion which ensued several members of the society took part, and Mr. Bennett having briefly replied the meeting adjourned.

LIFEBOAT SATURDAY IN BRISTOL.—Oct. 29th was observed in Bristol as Lifeboat Saturday, and as a result nearly £300 was received for the funds of the society.

CAMBRIDGE UNIVERSITY.—At the election to the Council of the Senate held on Nov. 7th, the following were chosen to serve for four years: Heads of Colleges, Dr. Peile, Mr. Chawner; Professors, Dr. Forsyth, Mr. Ewing; Members of the Senate, Dr. Donald Macalister, Mr. R. T. Wright, Mr. F. Whitting, Mr. A. W. W. Dale. Dr. Macalister was at the head of the poll, and has already served for twelve years.

Reviews and Notices of Books.

A Treatise on Surgery by American Authors. Edited by ROSWELL PARK, A.M., M.D., Professor of the Principles and Practice of Surgery in the Medical Department of the University of Buffalo, &c. In Two Volumes. Vol. I.: General Surgery, with 356 Engravings and 21 full-page Plates, pp. 799. Vol. II.: Special or Regional Surgery, with 451 Engravings and 17 full-page Plates, pp. 804. 1897. Edinburgh and London: Young J. Pentland.

A TREATISE on surgery to which are attached such names as those of the well-known surgeons who have contributed to these volumes and which contains more than 1600 pages of text and more than 800 illustrations, is certainly deserving of the fullest and most careful consideration. This we have given to the work before us and we express the general impression which the perusal of the book has left on the mind when we say that it fully represents the high level of theory and practice which surgery has attained in the country from which it comes. The editor, Professor Park, has judiciously chosen for each section a surgeon well qualified to write on the subject, and though individual opinions occasionally show themselves, yet the general result is very homogeneous.

The whole of the section on General Surgical Pathology, which deals with inflammation and its results and the pathology of the blood, has been ably treated by the editor. He gives an interesting account of fat embolism, perhaps attributing to it more important results than are usually supposed to follow its occurrence. In describing the discharge from a "healthy granulating surface" Professor Park denies that it is pus, as its origin is essentially different, for he does not consider that it is due to the irritation of micro-organisms, but simply to excess of reparative material. This opinion, however, can hardly be maintained in view of the fact that an aseptic granulating surface under an aseptic non-irritating dressing has no discharge whatever.

A valuable chapter is that on Auto-infection, by the editor. It sums up our present knowledge of this recent but most important subject. In his account of Tetanus Professor Park mentions that the toy pistol with percussion-caps was in the United States a frequent cause of tetanus in children. For instance, in July, 1881, in Chicago, there were more than sixty deaths from tetanus among children who had been injured in this way. This led to the sale of these pistols being suppressed by law. Some excellent illustrations of actinomycosis are given in the section dealing with that disease, but in the treatment of actinomycosis no mention is made of the great value of potassium iodide.

Dr. John A. Fordyce of New York writes on Syphilis and Dr. W. T. Belfield of Chicago on Gonorrhœa; both of these chapters are decidedly good. The remaining surgical diseases are dealt with by the editor, who contributes a useful account of the surgical aspects and sequelæ of those diseases—such as the exanthemata—which usually come under the treatment of the physician. In speaking of the Etiology of Scurvy Professor Park mentions that he considers that beri-beri is largely due to absence of animal food. There is surely very little foundation for this opinion, and most of the evidence points strongly in favour of a bacterial origin of this disease. Minor Surgery and the Treatment of Hæmorrhage are well described by Dr. J. Parmenter of the University of Buffalo, and Dr. H. A. Hare of Philadelphia contributes the article on Anæsthesia. Dr. C. B. Nancrede of the University of Michigan is responsible for the chapters on Wounds and their Repair and their Treatment, and he gives a very good account of aseptic methods.

In the last section of the first volume dealing with Surgical

Digitized by Google

Affections of the Tissues the longest articles are those on Cysts and Tumours by the editor, and on Fractures and Dislocations by Dr. H. H. Mudd of St. Louis. Professor Park gives a very clear description of new growths, always a difficult subject for students, and many excellent illustrations from photographs of cases are to be found in this chapter. In the account of Villous Papillomata we are told that "they are strictly identical with chorionic villi"; although it is easy to see the writer's meaning, yet there is little doubt that the sentence quoted might readily be utterly misunderstood. Dr. Mudd's account of Fractures and Dislocations is very good, and we would only point out that "Lister's" long splint should be "Liston's." All the chapters in this section are excellent, but we would specially mention Dr. J. Ransohoff's article on the Diseases of Joints and their Treatment.

The second volume is devoted to Regional Surgery and is as satisfactory as the first; to it the editor has contributed a valuable account of the Surgical Diseases and Injuries of the Head. He limits the application of the phrase "concussion of the brain" to those cases in which no gross mechanical lesion is present and naturally finds that there are very few cases to which it becomes applicable. It is better on the whole to employ the expression as a useful clinical term for the group of symptoms present in cases after an injury to the head in which no signs of "compression" are present and yet the brain has suffered. The symptoms referred to are probably due to bruising of the brain with minute ecchymoses; in fact, the condition which the writer of this chapter has described under the title of "contusion" of the brain. In the description of compression it is mentioned that there is increased cerebral tension, the first effect of which is to drive some of the cerebro-spinal fluid out of the skull into the spinal canal, and, further, that there is a "less rapid flow of blood" through the brain, but it is not explained that as the intracranial pressure rises the amount of blood entering the skull diminishes until the anæmia of the brain resulting from this causes the coma which ensues. When the general intracranial pressure is equal, or nearly equal, to the arterial pressure in the internal carotid and vertebral arteries death must occur. The coloured plate illustrating the topographical anatomy of the cerebral cortex is very clear.

Dr. E. H. Bradford of Boston writes on the Surgery of the Spinal Column and Cord, a very good chapter, especially the part dealing with Pott's disease. Dr. Duncan Eve of Nashville contributes the section on the Heart and Blood-vessels, and Dr. D. B. Delavan deals with the Surgery of the Respiratory Organs; these chapters are well written. The Surgery of the Face and Neck is described by Dr. E. Souchon of New Orleans and is very satisfactory.

The name of Professor F. S. Dennis of New York is sufficient guarantee that the article on the Surgery of the Chest is all that it should be. Dr. A. D. Bevan's contribution on the Surgical Diseases of the Mouth, Tongue, Teeth, and Jaws is good but rather short. It is followed by an account of a new method of closing a cleft of the palate invented by Dr. Truman W. Brophy: it consists in using a modification of the quill suture, flat lead plates taking the place of the tubes. The important subject of the Surgery of the Abdomen occupies 70 pages and is written by Dr. Maurice H. Richardson of Boston with the assistance of Dr. Farrer Cobb. It must have been difficult to compress so large a subject into so small a space, but the result is satisfactory and up-to-date. Dr. Richardson also is responsible for the chapter on Hernia; it contains a reproduction of a photograph of that rare condition, an ischiatic hernia. Dr. C. B. Kelsey of New York gives a good account of the Surgery of the Rectum and Sigmoid Flexure; for hæmorrhoids he prefers Smith's clamp and cautery to all other methods, and he thinks that "so elaborate an operation" as Whitehead's is never necessary to cure any case of hæmorrhoids. He considers that the ordinary "syphilitic stricture" of the rectum is not really syphilitic, but the result of simple proctitis. Dr. W. T. Belfield of Chicago has written the chapter on Genito-Urinary Surgery and has given a very good description of this important branch of surgery in comparatively few pages. In describing the treatment of Hypertrophy of the Prostate the writer speaks well of double castration, but insists that it should never be performed until the bladder has been opened and explored by the finger, so that the operator may be certain that the symptoms are not due to a vesical calculus or tumour.

The section on the Surgery of the Female Reproductive Organs has been undertaken by Dr. James H. Etheridge of Chicago; he gives a somewhat brief account of Gynæcological Surgery. It should have been pointed out in the description of ovarian cysts that most of the unilocular cysts are derived from the parovarium and not from the ovary itself. The account of the various procedures for treating ruptured perineum is very complete, and a diagram shows well the incisions in the different methods by means of superimposed outlines.

Dr. Charles B. Parker of Cleveland, Ohio, deals with the Surgical Diseases and Injuries of the Breast. This article is illustrated by some excellent photographs. Professor Rudolph Matas of New Orleans describes Amputations, and all recent methods are included. In the history of the methods of amputation it is hardly correct to speak of Celsus as the "prince of Greek physicians," as, though we know comparatively little about him, he certainly wrote in Latin and lived in Italy. For amputation at the hip-joint the writer prefers Wyeth's method, in which the hæmorrhage is controlled by a rubber tourniquet held in place by two long steel pins which transfix the thigh close to the hip. In the statistics of amputations which are given no distinction is made between amputations for injury or for disease, or between primary and secondary amputations. As on these points depends the whole value of statistics in this subject no conclusions can be drawn from those quoted.

Orthopædic Surgery has a section to itself, contributed by Dr. R. W. Lovett of Boston. The account is rather compressed, but may be taken as fairly representative of modern practice.

The most striking portion of Dr. Arpad G. Gerster's article on Plastic Surgery is the series of diagrams illustrative of the methods by which defects of the skin can be made good; the whole chapter is satisfactory.

Dr. C. S. Bull of New York contributes the section on the Surgery of the Eye, but he mentions in a preface that only the more common conditions and those which are likely to be met with in general practice are described, and comparatively little notice has been taken of operative technique except in regard to operations on the eyelids, as all operations on the eyeball are better left to the care of the ophthalmic surgeon. Even with these limitations the article occupies nearly 50 pages and is as complete as is needed in a work on general surgery.

In Dr. Clarence J. Blake's contribution on the Surgery of the Ear a useful summary is given of the chief operations on the middle ear. The volume concludes with a chapter by the editor on the Application of the Roentgen Rays to Surgery. Each volume has its own index and a general index is given in the second volume. The several articles vary greatly as to the number of references given, but many of them are abundantly supplied with these useful aids to study. As we have mentioned already nearly 800 illustrations adorn the pages. The printing and general get-up of the work are excellent.

The Principles and Practice of Medicine. By WILLIAM OSLER, M.D., LL.D. Edin., F.R.S., F.R.C.P. Lond., Professor of Medicine in the Johns Hopkins University and Physician-in-Chief to the Johns Hopkins Hospital, Baltimore. Third Edition. Edinburgh and London: Young J. Pentland. 1898. Pp. 1181.

THIS work is already so well known that no recapitulation of its scope is necessary in a review. But the present rate of progress of medical science necessitates frequent revision of text-books, and for the purpose of coping with these advances the present edition has been wholly recast—notably is this the case in the classification of diseases. Many readers, no doubt, will be surprised to find pneumonia and rheumatic fever placed amongst the "specific infectious diseases." With this classification we agree so far as concerns the former. Pneumonia is defined as "an infectious disease characterised by inflammation of the lungs, toxæmia of varying intensity, and a fever that terminates abruptly by crisis. Secondary infective processes are common." Dr. Osler is known for the great originality of his writings and for having the courage of his convictions. He is by no means the first observer to suggest that pneumonia should be classed amongst the specific fevers; but, as far as we are aware, he is the first who has so classified the disease in a text-book of general medicine. The section on Etiology, which supports this contention, is couched in terse phraseology, but contains all that is necessary for the student and practitioner and is devoid of redundant arguments. Dr. Osler goes still further in writing on Broncho-pneumonia, a disease generally considered as a purely inflammatory one, for we find the following: "All forms of broncho-pneumonia depend upon invasion of the lung with microbes and it would have been more consistent to place them with lobar pneumonia among the infectious disorders, but it is well, perhaps, to defer this until the bacteriology of the different varieties has been more fully worked out."

"Rheumatic fever" is defined as "an acute, non-contagious fever dependent upon an unknown infective agent and characterised by multiple arthritis and a marked tendency to inflammation of the fibrous tissues." The arguments in favour of this definition are likewise very lucidly given, and are based (*a*) on general evidence, such as its epidemic and seasonal occurrence; (*b*) on its clinical features, such as their similarity to those of septic infection; and (*c*) on special evidence, especially the bacteriology of acute rheumatism; but on this point the evidence is conflicting, and no positive proof has yet been offered of the constant association of any special micro-organism with the disease, and we would prefer to wait for further testimony before countenancing so bold a departure in medical classification.

Much new matter has been incorporated in the section on typhoid fever, and we note particularly the grouping of the various types. "Typhoid fever," says Dr. Osler, "is no more primarily intestinal than is small-pox primarily a cutaneous disease. We may recognise the following groups: 1. Ordinary typhoid fever with morbid enteric lesions. An immense majority of all the cases are of this character. ..... 2. Typhoid septicæmia, a general infection with the bacilli without special local manifestations ..... the diagnosis may rest upon the existence of the Widal reaction and the demonstration of the bacilli ..... 3. Typhoid fever with localisations other than enteric ..... The organs attacked may be the lungs, the spleen, the kidneys, or the cerebro-spinal meninges ..... 4. Mixed infections." All observers who have had a large experience of typhoid cases will probably agree with the author in this classification.

We commend Dr. Osler's remarks on the Value of Vaccination to the careful consideration of those whose opinion on the subject may be undetermined. Equally interesting are his comments on the Communicability of Leprosy. This matter is receiving much attention at the present time, a committee having just been appointed by the Royal College of Physicians of London to inquire into the evidence which has been accumulated. Dr. Osler remarks that while it is highly probable that leprosy may be contracted by accidental inoculation the experimental evidence is as yet inconclusive.

Much new matter will be found in the sections on Diseases of the Blood and Heart, and in these and similar sections on the Lungs and Kidneys the student will find set forth in decisive terms everything that is necessary for examination purposes. The paragraphs devoted to Treatment are especially noteworthy. The student or practitioner is not confronted with a number of drugs which have been suggested in certain diseases, but only those are recomended which have stood the test of experience. The section on Diseases of the Nervous System has been rearranged and an attempt has been made to group the diseases in accordance with the modern conception of the anatomy and functions of the part. Thus, system diseases—sensory, motor, and the two combined—are first considered, then diffuse diseases of the nervous system, such as affections of the meninges. Next diffuse and focal diseases of the spinal cord, followed by similar affections of the brain. Then we find diseases of the peripheral nerves, general and functional diseases, and, finally, vaso-motor and trophic disorders. In conclusion, we can cordially recommend Dr. Osler's text-book as one of the best in the English language. It is a volume which is much required, containing all that is necessary with regard to theory, but at the same time being essentially practical.

The Mineral Waters and Health Resorts of Europe. By HERMANN WEBER, M.D. Bonn, F.R.C.P. Lond., and F. PARKES WEBER, M.D. Cantab., F.R.C.P. Lond. London: Smith, Elder, and Co. 1898.

THIS is a new and enlarged edition of "The Spas and Mineral Waters of Europe," which was published not long ago. The additions made in the present volume include two new chapters on "Inland Climatic Health Resorts" and "Grape Cures, Milk-and-Whey Cures, Sanatoria for Dietetic and Special Methods of Treatment, and Sanatoria for Phthisis" respectively. In the arrangement of the spas of any one group the plan followed is to select two or three typical examples of the group and then to consider the remaining members of the group more briefly in "political geographical" order. Thus Wildbad and Ragatz represent the simple thermal waters, Spa, Schwalbach, and St. Moritz the chalybeate waters, and Ems and Royat the muriated alkaline waters, and so on. The information given is fairly full, considering the limits of the work, and extremely accurate. We have not been able to detect any error of importance. The estimate given of the value of balneological and climatic treatment is eminently sober and judicious, all extremes being avoided and every variety of treatment receiving due consideration. In dealing with such controverted questions as the Nauheim treatment of heart disease, the Karlsbad treatment of diabetes, and the Aix-la-Chapelle methods in syphilis, the authors show admirable judgment and good sense. The long chapter upon "Different Diseases and Morbid Conditions with respect to the Selection of Mineral Waters, Climates, Exercises, &c.," is an excellent piece of writing and contains a vast amount of well-digested information and valuable advice. If we have any fault to find with the general scheme of the work it is that spas and mineral waters receive disproportionate attention, while only relatively meagre space is allotted to such resorts as Davos, Falkenstein, Nordrach, &c. No doubt considerations of space have had great weight with the authors, but in future editions we think the special sanatoria for pulmonary tuberculosis might fairly claim fuller consideration. In a work which is on the whole a model of

Digitized by Google

accuracy even trifling errors naturally strike the eye. Thus, Roncegno and Levico are described in one part of the work as being "in the Austrian Tyrol" and in another part as being "in Italy." Contrexéville is described as distant "thirteen hours by train from Paris." These, however, are trifles. In the account of special marine sanatoria for "scrofulous" children no mention is made of Italy. We can warmly commend the book to the practitioner who desires a trustworthy and compendious guide to the large subject of mineral waters and climatic treatment but who does not want an exhaustive discussion of these questions. Within its limits this work has no rival that we know of. A therapeutic index would be of service and might be added in the next edition.

LIBRARY TABLE.

The Day's Work. By RUDYARD KIPLING. London: Macmillan and Co. 1898. Price 6*s*.—It is not usual with us to review a work of fiction other than one written by a medical man, but Mr. Kipling's latest collection of stories deserves more than a passing notice from us on account of two of them—namely, "The Bridge-builders" and "The Tomb of His Ancestors." The first details the building of a railway bridge over the Ganges and how when it was all but finished the great river arose in her might, coming down in flood to destroy the result of all the toil and labour. Then we hear, how the engineer and the foreman of the works, who was a native, sat and watched to see what would happen. Neither could eat and so the native gave his superior officer some opium. "Findlayson stood with his chin on his chest thinking. There was one point ..... that he had not fully settled in his mind. The figures would not shape themselves to the eye except one by one and at enormous intervals of time. There was a sound rich and mellow in his ears like the deepest sound of a double-bass—an entrancing sound upon which he pondered for several hours as it seemed." After this he found himself in a boat and considered how easy it would be to step out on the water and so be borne by the rushing stream to the shore. But "It needed only an exertion of will for the soul to hurl the body ashore as wind drives paper; to waft it kite fashion to the bank. Thereafter ..... suppose the high wind got under the freed body? Would it tower up like a kite and pitch headlong on the far-away sands or would it duck about beyond control to all eternity? Findlayson gripped the gunnel ..... for it seemed that he was on the edge of taking flight before he had settled all his plans..... In his mind he had already escaped from the boat and was circling high in air to find a rest for the sole of his foot. His body—he was really sorry for its gross helplessness—lay in the stern." He then argued with himself that he was on shore, but that Findlayson, "poor beast," would be drowned. "I'm on shore already, why doesn't it come along?" Now, anybody can realise the opium enthusiasm, but what strikes us in these passages is the wonderful way in which Mr. Kipling has put the sensations down on paper. This is the faculty in which he is so pre-eminent—the ability to realise for others circumstances and scenery. To take an instance of a slightly different character, anyone who has ever been in an Oriental mountain country has only to read the description of the hill village in the "Miracle of Purun Bhagat" to have it all brought back—the sights, the sounds, the very smells are present as we read. In "The Tomb of His Ancestors" we find an account of a mode of procedure which it would be eminently satisfactory to see applied to conscientious objectors. The fiat had gone forth that a certain tribe were to be vaccinated, and the members thereof, being simple and ignorant, tied up the official vaccinator in bonds and destroyed the official calf. John Chinn, the descendant of the "ancestors," is the *Deus ex machinâ*. He was trusted by the tribesmen and he addressed them as follows: "'Ye know the small-pox who pits and scars your children so that they look like wasp combs. It is an order of the Government that whoso is scratched on the arm with these little knives which I hold up is charmed against her. All sahibs are thus charmed and very many Hindoos. This is the mark of the charm. Look!' "He rolled back his sleeve ..... and showed the white scars of the vaccination mark. 'Now, all these things the man whom ye bound told you. But being pigs ye did not believe, and so came I here to save you first from small-pox, next from a great folly of fear, and lastly, it may be, from the rope and the jail!'" These sound arguments had their effect and the whole tribe submitted. The two stories from which we have quoted are by far the best of the collection, although "William the Conqueror" and "Maltese Cat" come very near them. The Indian or Afghan *milieu* is the one to show Mr. Kipling at his best.

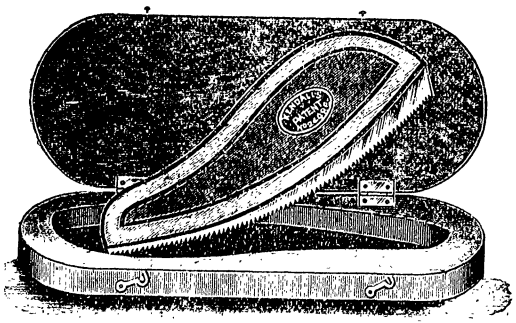
The Transactions of the Society of Anæsthetists. Vol. I. London: Published for the Society by the Medical Publishing Company, Limited. 1898. Pp. 171. Price 5*s*.—Some five years ago the anæsthetists of London formed themselves into a society for the purpose of encouraging the study of the subjects connected with their professional labours. The volume before us is the first one which the society has issued. It contains the Transactions for the year 1897-98, with the exception of the opening address delivered by the President, which appeared in THE LANCET of Nov. 27th, 1897. No collected records of the society's transactions have appeared until the present. Of the five sections of the book some deal with practical matters and we find that most of the newer methods and apparatus are described, notably those recently introduced with the view of maintaining anæsthesia by giving nitrous oxide gas through the nose. It has been said that the skilled anæsthetist should be an educated physician, a ready surgeon, and a physiologist rolled into one. In this book we find evidence that the society attempts at least to give its members an opportunity of hearing the views of physiologists as well as physicians and surgeons upon the subject of chloroform and ether. Professor Waller's now well-known experiments on the effects produced on isolated nerve by the anæsthetic vapours are recorded, and Professor Schäfer's views upon the physiological antidotes to chloroform are given. In the course of a most interesting discussion upon the best methods of Resuscitation in Emergencies under Anæsthetics excellent speeches were made — Dr. Bowles dealing with the different modes of performing artificial respiration, Dr. Silk with the antidotal employment of strychnine, and Mr. Harold Barnard with that of hydrocyanic acid and the effects of posture whereby the loss of the check action of the splanchnic areas is compensated and bulbar anæmia avoided. Not the least useful parts of these Transactions are those which deal with cases of danger, death, or difficulty, which occurred in the practice of members of the society and which were brought forward for discussion and elucidation. The volume is clearly printed, has illustrations, and forms a compendium of modern work in anæsthetics which no one interested in the subject can well afford to be without. We congratulate the society upon its first literary venture and hope to see equally good material in succeeding volumes with the addition of an index to facilitate reference.

Aerztliche Versicherungs-Diagnostik der Vollwertigen und der Minderwertigen Leben (*Life Assurance: The Medical Diagnosis of Good and Doubtful Lives*). By Dr. EDWARD BUCHHEIM.—The publishing firm of Herr Alfred Hölder at

Digitized by Google

Vienna has recently issued the above work by Dr. Edward Buchheim. The author, who is the Principal Physician of the Allgemeiner Beamten-Verein at Vienna, is well known in Austria and Germany as an authority on the subject of life insurance from a medical point of view, and his present book is a timely expansion of his publication some ten years ago on the same subject.

JOURNALS AND REVIEWS.



The Phonographic Record for November contains, in addition to notes of a fatal case of laparotomy for perforated gastric ulcer, an article by Dr. E. B. Gray upon the New Edition of Phonographic Outlines of Medical Terms, reviewed in THE LANCET of Oct. 15th, and a discussion upon Chronic Disease of the Uterine Appendages, taken from the pages of one of the circulating manuscript magazines of the Society of Medical Phonographers. Rest, hot vaginal douches, glycerine plugs and saline aperients, the treatment of uterine abnormality, and administration of hydrastis canadensis, salix nigra, hamamelis, ergot, and bromides sum up the measures adopted. Removal of the appendages is mentioned in deprecatory terms.

The Practitioner.—The November number of this journal is a very interesting one. Among the editorial paragraphs of the month is a sensible one on that ridiculously misnamed form of lunacy known as Christian Science. The editor rightly says that although the practitioners of this form of therapeusis are not amenable to the law for their "purely mental therapeusis" yet that if they prevent medical treatment they may then be fairly held responsible. Among the original papers are a clinical lecture by Dr. Patrick Manson on the Parasite of Malaria and a paper by Dr. Page May on Sulphur Treatment during the Winter in Egypt, dealing mainly with the springs at Helouan. The Medico-Literary Causerie deals with the late Wilhelm Meyer.

New Inventions.

SAW FOR REMOVING PLASTER-OF-PARIS AND OTHER CASINGS.

MR. E. G. KENDALL, of 53, High-street, Harborne, Birmingham, sends us a specimen of a saw which he has recently constructed for the removal of plaster-of-Paris and other casings. The saw has been made to obviate the use of

pliers, knives, acids, and other ill-adapted weapons, the shape of the blade being so designed that the toothed edge of the saw will enable the operator to cut through casings of any thickness without injuring the flesh of the patient.

A NEW MEDICINE BOTTLE.

MR. S. THISTLETHWAITE, of 35, Market-street, Manchester, sends to us for inspection an eight-ounce bottle and a one-drachm vial, the feature of which is that their necks are of the same size and therefore require the same sized cork. The invention has for its objects the saving of time, expense, and annoyance to medical men and druggists when dispensing and consequently merits respect from us, but we are not certain that the convenience of the innovation is quite as obvious to everyone as it may be to the dispenser. We have tried the effect of pouring water from the eight-ounce specimen and found the narrow neck a decided obstacle to an even flow. The fluid had a tendency to come in squirts which might make the measuring of an accurate dose a rather difficult task to the nurse, patient, or patient's friends. This being so with an eight-ounce bottle we wonder what sort of flow would issue from a forty-ounce bottle, up to which size the inventor is making bottles with a uniform neck. There is not much demand in medicine for bottles containing as much as two pints, but when they are wanted they are generally intended to hold lotions or antiseptic solutions to be used freely. We fear that a bottle whose speciality is to deliver *guttatim* a fluid that is wanted in large quantities will never achieve a vogue among medical men or nurses, however easy it may be for a dispenser to find a cork for it.

THE ROYAL COLLEGE OF SURGEONS OF EDINBURGH AND THE ARMY MEDICAL SERVICE.

THE following memorial has been presented to Lord Lansdowne by the Royal College of Surgeons of Edinburgh:—

To the Right Honourable the Marquess of Lansdowne, K.G., Her Majesty's Secretary of State for War.

The Royal College of Surgeons of Edinburgh wishing to encourage its Licentiates to regard the Army Medical Service more favourably than they have done in recent years has had under consideration the regulations for admission to the service, and after discussion at a meeting of the Fellows of the College has committed to us, its President and Council, the duty of respectfully bringing under your lordship's notice its opinion in regard to certain changes which it deems necessary. The College gratefully appreciates the interest your lordship has shown in the well-being of the Army Medical Service, and, along with your lordship, recognises the importance to the efficiency of the army of having a medical department highly educated, fully manned and equipped by the best men sent out from our colleges and universities. With the view of obtaining such a class of candidates for the Army Medical Department we beg most respectively to submit:—

FIRST. *In regard to the conditions for admission to the service.* — The present regulations for the competitive entrance examination do not appear to us well adapted to secure the best men; too much importance seems to be given to elementary subjects and too little to the practical and clinical work which now occupy the latter years of professional study. Since Jan. 1st, 1892, by order of the General Medical Council, the course of professional education has been extended in all cases to five years, with the recommendation that the fifth year, thus added, should be devoted to clinical work. By the regulations of the various universities and other licensing bodies the examinations in elementary subjects, including chemistry, pharmacy, anatomy, and physiology, take place at the end of the first, second, or third year of study, thus allowing the fourth and fifth years to be devoted to the branches of surgery and medicine and midwifery, and to clinical work in hospitals and dispensaries.

Intending candidates for the army competitive examination who have qualified themselves for the active duties of their profession are thus deterred from entering the competition, which either necessitates a return to elementary studies or a recourse to a "crammer" in order to acquire such kind of knowledge as will gain marks at the competitive examination. By this system the best men will not be obtained for the service. While we hold that a thorough knowledge of the fundamental subjects of anatomy and physiology is essential, it must be remembered that all candidates have already been tested in these subjects in a more practical manner than that employed at the army

Digitized by Google

competitive examination or than can be secured apart from dissecting rooms and college museums and laboratories. We would also observe that abundant opportunities occur in the course of any examination in surgery and medicine for testing the practical knowledge of anatomy and physiology. We would therefore venture to suggest that "chemistry and pharmacy and a practical knowledge of drugs" and "anatomy and physiology" be no longer retained as *separate* subjects in the army competitive examination.

The subject of pathology, including bacteriology, has of late years become of great importance in surgical and medical study, as well as in that of hygiene, and might be made useful as a critical test of the acquirements of candidates. The importance of such knowledge and of the accompanying familiarity with the use of the microscope to the army medical officer is manifest. Of this there have recently been presented notable examples in the recognition of the causes of typhoid fever, cholera, and bubonic plague, &c., and in their prevention and treatment. It is disappointing and deterring to our best qualified men, who have devoted the latter part of their course to such studies in their clinical work, to find them not recognised in the army competitive examination.

We do not forget that the army surgeon on probation has to undergo a course of further instruction in such subjects at the Army Medical School, which cannot but be useful to him in the special application of such knowledge to the circumstances of military duty, but we submit that the previous more general study of these subjects should be recognised in the army competitive examination. We are therefore of opinion that the compulsory part of the competitive examination should be limited to those subjects with which the student is mainly concerned in his last two years of study—viz., surgery and medicine—surgery to include operations on the dead body and the application of surgical apparatus; medicine and surgery to include pathology and hygiene and the examination at the bedside of patients, medical and surgical. We would further suggest that the number of marks obtainable in the practical subjects of surgery and medicine should be increased in proportion to those obtainable in the voluntary subjects of science and languages. We desire to mention our cordial approval of the intimation to candidates for admission into the Army Medical Service that they may be rejected for bad spelling or composition. Among the large number of preliminary examinations in general education recognised by the General Medical Council there is reason to believe that sufficient values are not always given to examination in English. It is not necessary to dwell on the injurious influence that such deficiencies in preliminary education must have on the social position of an army medical officer.

SECOND. *The non-existence of a system of "Study Leave."*—In the Army Medical Service this is a serious impediment to the efforts of the ordinary medical officer to keep abreast of the progress of medical science. Unless he happen to be stationed where there is a medical school it is not possible for him to become practically familiar with the improvements in the ever-advancing science and art of surgery and medicine. Such opportunities are ever present at all medical schools, but, in addition, there are now at all the important medical schools courses of instruction, termed "Post-graduate Courses," to which practitioners in civil practice have recourse in order to learn what is new in surgery and medicine. Still more are such opportunities required for most of the medical officers of the army, cut off as they necessarily are for long periods from being in relation with medical educational centres. Such opportunities can rarely be attainable during foreign service, but on returning from such service, as well as after some years of ordinary home service, we regard it as essential that the army medical officer should have a period of leave afforded him for practical study, and that some advantages be accorded him in recognition of such further study, which may act as a stimulus to him to avail himself of it. We would also venture to remind your lordship that the promise made by a previous Secretary of State for War that the Examining Board for the Army Medical Department should include representatives from the medical schools of Scotland and Ireland, as well as from those of London, has not been implemented to the extent we desire.

We beg most respectfully to submit to your lordship our opinion that if improvements on the lines indicated were introduced the army medical service would be better fitted to attract young medical men of talent and to attain to that state of high efficiency which it is alike the duty and interest of the country to secure.

On behalf of the President and Council of the College,
(Signed) JOHN CHIENE, President.

Royal College of Surgeons of Edinburgh, July 11th, 1898.

The following reply has been received from the War Office:—

To Professor John Chiene, President of the Royal College of Surgeons of Edinburgh.

SIR,—With reference to your letter of 13th July last, forwarding a memorial from the Royal College of Surgeons of Edinburgh in regard to the medical service of the army, I am directed by the Secretary of State for War to inform you that he has given his most careful attention to the representations therein set forth. In regard to the question dealt with in the first part of the memorial—viz., that of the subjects to be included in the competitive examination for entrance into the Royal Army Medical Corps—Lord Lansdowne admits that the arguments adduced are not without force, but he has come to the conclusion that it is not at the present moment advisable to make any change in the subjects prescribed for the examination. With the opinions expressed in the second part of the memorial, as to the desirability of a system of "study-leave," Lord Lansdowne fully sympathises, and he has already given his sanction to the grant of leave for this purpose; but owing to the unusually severe demands which have been made upon the *personnel* of the Royal Army Medical Corps at a time when it was considerably below its normal establishment it has not been found possible to give effect to this privilege to the extent to which he would desire to do so. It is hoped, however, that the grant of such leave on a more liberal scale may shortly become practicable. With reference to the last paragraph but one of the memorial, in which it is stated that the promise made by a previous Secretary of State for War, "that the Examining Board for the Army Medical Department should include representatives from the medical schools of Scotland and Ireland, as well as from those of London," has not been adequately fulfilled, I am to call the attention of your College to the composition of the present Board of Examiners, two of whom (out of a total of four)—Professor McCall Anderson, Scotland, and Professor Cunningham, Ireland—belong to the schools of those countries, and to state that such a composition, in the opinion of Lord Lansdowne, constitutes an adequate fulfilment of the promise referred to. I am to add that every attempt will be made to secure upon all occasions a fair representation of the different schools, but the eminence of the examiners and the public confidence which they inspire must be the first consideration.

I have the honour to be, Sir, your obedient servant,
(Signed) R. H. KNOX.

War Office, London, S.W., October 7th, 1898.

QUEEN'S COLLEGE, BELFAST.—The following is the scholarship list which was posted in the College Hall on Nov. 1st for session 1898–99 in the Faculty of Medicine: Fifth Year—Medicine and Pathology: William Matthew Hunter; Surgery and Midwifery: John Edmund Clements, Fourth Year: John Alexander Douglas Radcliffe; John Campbell Rankin; John Elder M'Ilwaine, a prize. Third Year—Albert Lytle Black; David M'Mordie. Second Year—Henry Mulrea Johnston; Thomas Carnwath; John M'Clatchey, a prize. First Year—Literary—John Stanley Pyper.

TAUNTON AND SOMERSET HOSPITAL.—On Nov. 2nd Lord Wolseley unveiled at Taunton a bronze bust of the late Lieutenant-Colonel Chard, V.C., erected with funds subscribed to perpetuate the memory of the hero of Rorke's Drift. Lord Wolseley afterwards presented a cheque for £600, being the balance of the fund, to General Emerson, who represented the Taunton and Somerset Hospital, and this sum is to be used for the purpose of endowing a bed in the hospital for a soldier or his wife or child. Colonel Heyar, the honorary secretary of the fund, mentioned that £300 was still required to complete the endowment of the bed, and added that he had reason to believe the people of Natal would shortly send a donation for that purpose.

THE LANCET.

LONDON: SATURDAY, NOVEMBER 12, 1898.

ON Thursday, Nov. 17th, will be held the annual meeting of the Fellows and Members of the Royal College of Surgeons of England. The progress of reform in the College is, as it has ever been, extremely slow, and we can well understand that some of its supporters despair of it entirely. Fourteen years have now elapsed since the Council decided to call a yearly meeting of the Fellows and Members of the College and to submit to them the annual report. This was a very small concession for the Council to make, but it was obtained only after a long and severe struggle, and at first the meetings were of little value, for nothing more than limited discussion was allowed. In time, however, resolutions were permitted, but only under oppressive restrictions which deprived them of much of their value. To-day a little more freedom has been granted both as to the terms of the motions brought forward at the meetings and as to the limits of the subsequent discussions. Something more than five years ago the Council, after many misgivings and much consultation with its legal advisers, decided to call half-yearly meetings of the Fellows apart from the Members, and further to call separate meetings of the Members, whenever in the opinion of the Council it was advisable. The introduction of voting by post for the election of members of the Council is also to be accounted a measure of reform. But these changes, few and comparatively unimportant though they be, represent the total amount of reform which has been wrung from a reluctant Council in the fifty-six years which have passed since the establishment of the Fellowship. That act cannot be looked upon as in any way a true reform. Though the benefits resulting from the formation of a higher grade of surgeons have been great, and it has doubtlessly led to the improvement and advancement of the science and art of surgery, yet the political outcome of the creation of the Fellowship has been in effect the restriction of the franchise to a comparatively small body of men, and politically it was a retrograde step. Far be it from us to belittle the standing or intelligence of the Fellows — they have by their training and their experience a wide and accurate knowledge of many parts of professional education; but neither the training nor the experience of the greater number of the Fellows renders them capable of judging of the professional needs of the majority of the Members of the College. Even were it not so; if the Fellows and the Council elected by them were indeed fitted to appreciate the requirements of the Members, if every act and every resolution of the Council were all that could possibly be devised for the benefit of the Members, even then the anomaly and inadequacy of the present constitution of the College would remain conspicuous. By the express words of the Charter, by the very admission of the Council itself, the Members form part of the body corporate, and yet in vain do they appeal for a share in the government of the College. Those who are the true constituents have no voice, either direct or indirect, in the management of the institution to which they belong.

Early in last year the Council solemnly put forth their claim to represent the whole of the body corporate of the College, and therefore the Members as well as the Fellows, but it is difficult to believe that this pronouncement deceived even any member of the Council who voted for it at the meeting at which it was carried. There are fewer than 1200 Fellows; there are more than 17,000 Members of the College of Surgeons: can it be seriously said that those 1200 Fellows represent the Members, who are fourteen times as numerous? The Council has admitted that the Members are a part of the body corporate of the College, and no satisfactory reason has ever been advanced why they should not take part in the election of the Council. We disclaim entirely and emphatically any imputation of unfairness against the individual members of the Council—they are all, whatever opinions they may hold, desirous only of doing what they think best for the interests of the College—and, moreover, we are of opinion that no small proportion of the members of the Council really favour the extension of the franchise. We simply point out their unsatisfactory position. It is often urged that the Members have no *legal* right to the powers they claim, and this must be admitted, but they possess what is of more value than a legal right, they have a moral right, and when legal and moral rights come into conflict the final victory always remains with the moral right. Moreover, the Members of the College contribute the major part of its revenues, and but for their pecuniary contributions the College would soon have to curtail its huge annual expenditure on the museum and library. An argument which is also employed is that since every Fellow of the College is also a Member, therefore some Members at least are represented on the Council. We only mention this in order to show how logically weak the defenders of the present state must be to be willing to employ such a puerile argument. Again, it has been said that the privilege of voting at the election of members of Council has acted as a great inducement to many to pass the examinations for the Fellowship. We think we may safely challenge the upholders of the present system to produce any Fellow of the College who was influenced in even the slightest degree by the privilege of voting to aspire to the Fellowship.

For the present we may leave out of consideration the question as to how the Members should be represented on the Council, whether by Fellows or by Members, or by Fellows or Members indifferently. These are weighty matters and in due time they will come up for discussion and ultimately for solution, but at present they may stand aside and await their turn. The exact number, too, of representatives on the Council to be allotted to the Members and whether they should be in place of a corresponding number of the present members of Council or in addition to the twenty-four representatives elected by the Fellows, though questions of great importance, can well wait until the right of representation has been conceded. *The Members must have the power of voting at the*

Digitized by Google

election of the Council. This desired consummation, however, cannot be obtained without persistence on the part of those who are interested in the matter. There is unfortunately a great deal of apathy amongst the Members; they do not seem to feel that the subject concerns them at all; many are too busy with their practices, many others live too far away for active coöperation, but even after allowing for all who are absent on account of these reasons there are very many who never put foot within the College buildings. Time after time at the annual meetings of Fellows and Members only a few are present, and of these some are Fellows. The Members must bestir themselves; they must attend in full numbers at the meetings which are at present vouchsafed to them; they must show by their votes that they are thoroughly in earnest and that they intend to demand the suffrage persistently until it is granted to them; but withal this must be done with courtesy. Vulgar declamation and the attribution of unworthy motives to the members of the Council can only tend to estrange the sympathy of many Fellows and members of the Council who now are fully on the side of the Members. In time the looked-for end will come. No one can prophesy when, but come it must if the Members, who so truly deserve the power of voting for the election of the Council, show by their actions and their words that they desire it also. The Royal College of Surgeons of England cannot suffer. Firmly supported by all its Members as well as all its Fellows, it will fulfil more thoroughly than at present the purpose of its existence.

IT is a curious fact, the truth of which is so generally recognised that it almost amounts to a platitude, that disastrous occurrences which take place in our midst at once rivet our attention, whereas if they take place at a distance they fail in a great measure to do so. The explanation of this is not far to seek, for if a disaster occurs at a distance more or less remote from ourselves it does not endanger our lives or jeopardise our interests. Moreover, any evil which is at all chronic or continuous soon loses the effect which its first incidence produced. Be all this as it may, however, the recent history of India has been singularly calamitous, for famine, plague, pestilence, and war have followed one another in quick succession. When the news of the outbreak of plague first reached this country some three years ago, and whilst the number of cases was still comparatively limited, we could not shut our eyes to the gravity of the intelligence, although we were naturally desirous of avoiding the creation of any feeling of panic in the initial stage of an evil, when the extent of it in the future could only be a matter of conjecture and hypothesis. The subsequent progress of events has shown how serious has been the continuance and spread of the epidemic of plague in the Bombay Presidency and elsewhere in India. The Government of that country finds itself in the extremely difficult position of being placed between the opposing forces of sanitation and political expediency. Attempts to suppress or limit the spread of the disease by restrictive measures—necessarily of a severe character if they were to be of any use—have not unnaturally awakened a spirit of antagonism on the part of the native population and given rise to a good deal of disaffection.

Moreover, our knowledge of plague at the beginning of the epidemic was small and empirical, mainly derived as it was from the historical records of it in the past rather than from any scientific, clinical, or practical observation. The subject has, however, now been studied with the keenest interest from all sides and has been investigated with all the aids which the more recent and precise methods of scientific research could bring to bear upon it. Nor has the investigation comprised only clinical, bacteriological, and experimental work in the laboratory. The most important step was the first one—that of the discovery of the bacillus pestis by Dr. KITASATO and Professor AOYAMA of Japan during the preceding epidemic of plague at Hong-Kong. The accuracy of their discovery has been completely verified by the late lamentable occurrences at Vienna. So far as that part of the investigation of plague is concerned we have complete proof, at any rate, that the bacillus of plague is veritably and indeed the cause of that disease and that it is capable of initiating an outbreak of plague of virulent type. While we can then take a firm stand upon this foothold of fact there still remains a great deal to be yet accomplished, some of which is of a very practical and important kind. We are still upon the threshold of the inquiry as to the natural history of the bacillus, the conditions favourable to its growth and development, and as to the best means of dealing with plague with a view to preventing or limiting its spread and of safeguarding a population or individuals against its attacks. We think, therefore, that the Government have very wisely decided to send a Commission to India, consisting mainly of scientific experts, to report upon the plague in that country, and that an excellent selection has been made for the purpose. Dr. THOMAS R. FRASER, F.R.S., Professor of Materia Medica and Clinical Medicine at Edinburgh University, has accepted the duty of President and with him will be associated two other scientific experts — Dr. WRIGHT, Professor of Pathology at the Army Medical School, Netley, and Dr. RUFFER, who has been for some time head of the Egyptian Sanitary Department at Cairo. Two officers of the Indian Civil Service, Mr. J. P. HEWETT, C.I.E., and Mr. A. CUMINE, both of whom have had much to do with recent plague affairs in India, have also been appointed to the Commission by the Government of India. The scope of the Commissioners' inquiries will include—(1) the origin of the different outbreaks of plague; (2) the manner in which the disease is communicated; and (3) the effects of certain prophylactic and curative serums that have been tried or recommended for the disease. The members of the Commission will reach Bombay towards the end of the present month.

It will be seen that the functions of the Commission are mainly of a scientific and technical character, and that matters of sanitary and medical organisation do not, therefore, fall within their province and purview. We may point out, however, that we have long thought and often said that the sanitary service in India might be remodelled with advantage. As far as our information extends

Digitized by Google

there is too much reporting and too little action and directness of aim. A new, increased, and more efficient machinery of a special kind seems to be required, designed somewhat on the lines of the public health organisation of this country, for investigating and dealing with the causes of disease and for supervising and controlling the methods of procedure and expenditure for public health purposes. We fully recognise the difficulties arising from the extent of country and the variety of peoples, their poverty, traditional conservatism, and racial, religious, and social prejudices, as also the need which exists for reconciling them to the Imperial Government — which, it must be remembered, is an alien Government. But when we think of all that is done in England, with its Local Government Board, medical officers of health, and sanitary inspectors, and compare it with what exists and is done in India the contrast is striking. However, as RUDYARD KIPLING says, "that is another story," but one with which the Government of India will sooner or later be brought face to face, if the time has not already come for it to make a beginning.

THE sittings of the Royal Commissioners were resumed on Monday last, and we continue our report of them. In view of the long break in the sittings it will be well to quote the "terms of reference" for our readers and to give also a brief summary of the proceedings. The terms of reference are as follows:—

"To inquire: 1. Whether, having regard to financial considerations and to present and prospective requirements as regards water-supply in the districts within the limits of supply of the metropolitan water companies it is desirable in the interests of the ratepayers and water consumers in those districts that the undertakings of the water companies should be acquired and managed either (*a*) by one authority, or (*b*) by several authorities, and if so, what should be such authority or authorities. To what extent physical severance of the works and other property and sources of supply of the several companies and the division thereof between different local authorities within the limits of supply are practicable and desirable, and what are the legal powers necessary to give effect to any such arrangements.

"2. If the undertakings are not so acquired, whether additional powers of control should be exercised by local or other authorities, and if so, what those powers should be.

"3. Whether it is practicable to connect any two or more of the different systems of supply now administered by the eight metropolitan companies; and if so, by whom, and in what proportion, should the cost of connecting them be borne, and what are the legal powers necessary to give effect to any such arrangement."

At the second meeting of the Commissioners Lord LLANDAFF, the Chairman, announced that the Commissioners accepted generally the findings of the former Royal Commission which was presided over by Lord BALFOUR of Burleigh. He said: "We have decided not to reopen the questions reported upon by the Royal Commission presided over by Lord BALFOUR of Burleigh, and, speaking generally, we accept the findings of that Commission." The BALFOUR Commission, it may be remembered, was appointed to report on the quantity and quality of the Metropolitan Water-Supply. It may be well to restate the terms of reference on which the BALFOUR Commissioners reported. They are as follows:—

"Whether, taking into consideration the growth of the population of the metropolis and the districts within the limits of the metropolitan water companies, and also the needs of the localities not supplied by any metropolitan company but within the watersheds of the Thames and the Lee, the present sources of supply of these companies are adequate in quantity and quality, and, if inadequate, whether such supply as may be required can be obtained within the watersheds referred to, having due regard to the claims of the districts outside the metropolis but within those watersheds, or will have to be obtained outside the watersheds of the Thames and the Lee."

The report issued by the BALFOUR Commission was a long and, in some parts, an argumentative document. The main decisions at which they arrived, however, are given in the following paragraphs of their report:—

"We are strongly of opinion that the water, as supplied to the consumer in London, is of a very high standard of excellence and of purity, and that it is suitable in quality for all household purposes."

"We are of opinion that an average daily supply of 40,000,000 gallons can be obtained from wells and springs in the chalk of the Lee Valley without affecting any material interests; but that if that quantity is exceeded it is probable that the springs and wells in the parts of the valley immediately adjacent to the wells and all the districts further down the valley may be injuriously affected."

"From wells in the chalk area on the south side of the Thames, in the district of the Kent Company, we are of opinion that a daily average supply of 27,500,000 gallons may be obtained."

"From the River Lee we are of opinion that with adequate additions to the present system of storage 52,500,000 gallons may be taken daily."

"We are of opinion that by the construction of storage reservoirs in the Thames valley, at no great distance above the intakes of the companies, it will be possible to obtain an average daily supply of 300,000,000 gallons without taking in any objectionable part of the flood-water."

The Royal Commission which is now sitting met first on Nov. 22nd, 1897, and at the time of its rising for the autumn vacation had sat thirty-one times. At these sittings the London County Council has occupied more than two-thirds of the time of the Commissioners. At the first three sittings evidence was given by Mr. H. L. CRIPPS, Parliamentary Agent to the London County Council. The fourth, fifth, sixth, and part of the seventh sittings were taken up by hearing the evidence of Sir ALEXANDER BINNIE, chief engineer to the London County Council. Sir ALEXANDER BINNIE gave evidence again at later sittings and his evidence occupied part of the twenty-second and the whole of the twenty-third and twenty-fourth sittings of the Royal Commissioners. Part of the seventh and the whole of the eighth and ninth sittings were occupied by evidence given by Mr. H. E. HAWARD, the Comptroller to the London County Council. Mr. G. L. GOMME, Statistical Officer to the London County Council, gave evidence at the tenth, eleventh, and twelfth sittings. The thirteenth, fourteenth, and part of the fifteenth sittings were occupied by taking the evidence of Mr. W. H. DICKENSON, Chairman of the Water Committee of the London County Council. Sir JOHN LUBBOCK, M.P.,

Digitized by Google

gave evidence at the conclusion of the fifteenth sitting and at the beginning of the sixteenth, and the remainder of the latter sitting was occupied by receiving evidence from Mr. C. A. WHITMORE, M.P., another County Councillor, whose evidence was completed at the seventeenth sitting. The latter part of the seventeenth, the whole of the eighteenth, and part of the nineteenth sittings were occupied by the evidence of Mr. GABRIEL PRIOR GOLDNEY, the Remembrancer to the City of London. The remainder of the nineteenth sitting was occupied by taking the evidence of Sir ARTHUR ARNOLD, another member of the London County Council and a late chairman. His evidence was concluded at the twentieth sitting, at which Mr. SHIRLEY F. MURPHY, Medical Officer of Health of the Administrative County of London, gave brief evidence. The remainder of the sitting was occupied by the evidence of Mr. G. F. DEACON, another witness employed by the London County Council. At the twenty-first sitting evidence was tendered on behalf of the vestries of Islington, Shoreditch, and Wandsworth. At the twenty-second sitting M. GASTON CADOUX, chef de bureau to the Prefecture of the Seine, gave evidence in support of the London County Council. The whole of the twenty-fifth and part of the twenty-sixth sittings were occupied by the evidence of Mr. R. M. LITTLER, Q.C., at that time chairman to the county council of Middlesex. At the twenty-sixth sitting evidence was given on behalf of the parish of St. Mary Abbott, Kensington; and Mr. COLLINS, a resident of Whitechapel, complained of the water-supply given by the East London Company during the years 1895 and 1896. The twenty-seventh sitting of the commissioners was occupied in hearing the evidence of Mr. JAMES BIGWOOD, M.P. for the Brentford division of Middlesex, and of Mr. E. J. HALSEY, chairman to the Surrey County Council. Mr. HALSEY, on behalf of Surrey, said that purchase by the London County Council was in the opinion of his council the very worst settlement which could be arrived at. At the twenty-eighth sitting no less than nine witnesses gave evidence. Mr. HOWARD MARTIN appeared for the Croydon Borough and Mr. SALTER WHITER for the Croydon Rural District Council; Mr. T. H. WATNEY gave evidence on behalf of the Borough of Richmond; Mr. G. J. COURTHOPE appeared for the Kent County Council; Dr. R. M. H. RANDELL for Beckenham in Kent, Lieutenant-Colonel CHARLES KIDD for the Dartford Urban District Council, Mr. A. T. WARING for the Dartford Rural District Council, Mr. F. H. NORMAN for the Bromley Urban District Council, and Mr. R. G. MULLEN for the Bromley Rural District Council. At the twenty-ninth sitting witnesses gave evidence on behalf of the Essex County Council, and of East and West Ham, Barking, and Leyton; and Sir JOHN EVANS, Vice-chairman of the Hertfordshire County Council, was briefly examined on a very important statement which he put in with regard to the water-supply of Hertfordshire. At the thirtieth sitting Mr. HENRY WEEDEN gave evidence on behalf of the Ilford Urban District Council, and Mr. F. G. BANBURY, M.P., a trustee and manager of the Stock Exchange, explained a scheme which had occurred to him as being the best method of purchasing the businesses of the London water companies. At the same sitting Mr. ALLEN STONEHAM, auditor of the accounts of the metropolitan water companies, explained his duties and how he carried them out. The latter part of the sitting and the whole of the thirty-first sitting was occupied by the evidence of Mr. R. E. MIDDLETON, who had acted as Assistant Commissioner to Lord Balfour's Commission, and who now gave evidence as a scientific expert on behalf of the London water companies.

From this point we shall continue the reports of the sittings from week to week.

LAST week we considered the case of JOHN LLOYD WHITMARSH as standing by itself; there is, however, an aspect of it which is attracting even more attention than the individual facts relating to the death of the unhappy girl ALICE BAYLY. Within the space of a few months two men, COLLINS and WHITMARSH, have been tried for murder at the Old Bailey, each having caused the death of a woman in the endeavour to unlawfully procure miscarriage. The one has been convicted of manslaughter and sentenced by the judge who presided at his trial to a term of penal servitude; while the other has been convicted of murder, sentenced to death, and subsequently reprieved by the Home Secretary, his ultimate fate being thus left in the hands of that official; and the question has naturally been asked by many whether in the two cases there existed any material facts to differentiate them in the eye of the law, or whether some defect in the law of England had resulted in an inequality in the administration of justice.

The law of murder is mainly common law undefined by statute, though interpreted and regulated by the decisions of generations of judges, and in the minds of the writers of the older law books there seems to have existed no doubt but that anyone who by an act done with intent to commit a felony, or by conduct which in his knowledge was likely to cause death and was therefore eminently dangerous in itself, killed another, was in either case guilty of wilful murder. This was carried so far that it could be said that if a man shooting at a fowl with intent to steal it killed someone inadvertently he would be guilty of murder, while it would be only a case of death by misadventure if the man had a right to shoot the fowl through being its owner or only did so out of mischief. It must be borne in mind, however, that this was in a Draconian age, when the fate of criminals, whatever their punishment, was regarded more callously in every way than now, and that, as capital punishment would be inflicted in many instances for the felony itself, the question whether owing to a death occurring incidentally the offence became that of murder was not of the same importance to anyone that it is now. In two conspicuous trials during the past thirty years—in that of BARRETT and others in 1868 for causing the numerous deaths resulting from the Clerkenwell explosion, and that of SERNÉ, who in 1887 set fire to his house for the sake of the insurance, causing the deaths of two of his children who were in it, the law of murder committed without direct intent to kill has been laid down by very eminent judges. We have taken from the summing-up of Sir FITZ-JAMES STEPHEN in SERNÉ'S case our definition of the usually accepted law, but both he and Lord Chief Justice COCKBURN in the Clerkenwell case followed up their general definition.

Digitized by Google

with one apparently modified to suit the requirements of a gentler age. Mr. Justice STEPHEN accordingly said: "I think that instead of saying that any act done with intent to commit a felony and which causes death amounts to murder, it would be reasonable to say that any act known to be dangerous to life and likely in itself to cause death done for the purpose of committing a felony, which caused death, should be murder." In result, the two cases now referred to differed much as those of COLLINS and WHITMARSH have done—BARRETT was convicted of murder and hanged, being the last person publicly executed in this country; SERNÉ, no question of manslaughter being apparently suggested to the jury, was acquitted, but afterwards tried for the arson, which he had clearly committed, and convicted of that less heinous offence. The fact that the crime of BARRETT had resulted in many deaths and caused the greatest excitement and horror in London, while that of SERNÉ was comparatively obscure and unimportant, suggests at once an element of human weakness in the verdict of one of the two, or rather three, juries concerned with these two trials, and before passing on to consider the law applying to COLLINS and WHITMARSH it is not out of place to point out that the same element may have had something to do with the different verdicts in their cases also. It will be remembered that in the case of WHITMARSH there was the dying declaration on which we commented last week, and the evidence and cross-examination of the prisoner. A feeling of greater certainty in his case may therefore have tended to give the jury confidence to return a verdict of murder, though all juries are in theory equally certain and confident. Apparently also, from letters that have been published, individual jurors did not realise that a death sentence would follow their decision, and these letters further accentuate what we have said as to the human element as distinct from the legal in verdicts.

Let us, however, now consider the principles of law laid down above with reference, in practice, to cases of criminal abortion. Of the application of the law in olden days there can be little question. Sir MATTHEW HALE[1] writes: "If a woman be with child and any gives her a potion to destroy the child within her and she take it and it works so strongly that it kills her, this is murder, for it was not given to cure her of a disease, but unlawfully to destroy her child within her, and therefore he, that gives a potion to this end, must take the hazard, and if it kill the mother it is murder and so ruled before me at Bury in the year 1670." And there is more recent authority to the same effect. When, however, we come to the present year we find that the Attorney-General gave the law to the jury in the trial of COLLINS much in accordance with the definition of Lord Chief Justice COCKBURN and Mr. Justice STEPHEN but, in the words of Mr. PICKERSGILL, M.P., who contributed an interesting letter on the subject to the *Times* last week, he "rode from start to finish for a verdict of manslaughter as against a verdict of murder," whereas Mr. Justice BIGHAM, an extremely clear-headed and able judge, presiding at the second and final trial of WHITMARSH, at which Sir RICHARD WEBSTER did not appear—after giving a similar definition of the law, clearly instructed the jury that in his view the application of the law to the facts before them must logically result in a conviction for murder. Now it is so difficult—taking into consideration the facts of each of the two cases and the necessary knowledge of each man as to the danger attending on his acts, performed in the circumstances in which they were performed—to discover differences between them that would warrant a different application of the principles laid down, that we are almost driven to this conclusion:—that by the common law the taking of life in the course of the unlawful procurement of abortion is murder; that the rule of law by which this comes to be so has had its application narrowed and its limits defined to suit the clemency of modern times; and that the question whether a case of death falls within the narrower limits or not depends in a measure on the view taken by the judge or the counsel for the prosecution; while as these guide but do not control the verdict the personal opinions of the individuals who compose the jury form another element of uncertainty. As a result two different verdicts have been returned in two practically indistinguishable cases, the carrying out of the sentence necessarily passed in the second being rendered impossible by the finding of the jury in the first. Similar cases may recur at any time with similarly conflicting results, and this element of uncertainty in the matter of a serious crime demands the attention of lawyers and legislators. Mr. PICKERSGILL, in the letter already referred to, urges the separating of cases of death through the procurement of abortion from other cases now governed by the same rule and recommends a short Act of Parliament for the purpose, giving examples from the codes of India, Italy, and Massachusetts, U.S.A., of the manner in which the crime in question is punished in those countries. It may, however, be found difficult to logically justify the differentiating deaths caused in the commission of one felony from those resulting from another; the legislative machine is not always easy to move and English law has always been inclined to resist codification. It would be easier—and such a course has, we believe, been suggested—to establish a consistent practice for the cases in question. We are inclined to think that the Treasury, which almost invariably prosecutes for such offences, should make it its established practice to indict for manslaughter only, the present Attorney-General being clearly of opinion that manslaughter is a possible alternative. This would produce uniformity and would eliminate the necessity for a jury (with the possible capital penalty before it) having to determine whether the attempt to procure abortion in a particular way is of itself dangerous or whether the prisoner acted with the knowledge or belief that life was likely to be sacrificed by it—questions which result in a jury having to decide on issues hard for jurors to grasp and difficult for evidence to elucidate. It would leave the ultimate punishment where it is now, for the death sentence is never enforced, but would make it in all cases the sentence of the judge trying the case; it would be in accordance with the trend of public opinion; and it would get rid of the feeling, abhorrent to Englishmen, that there is in some cases, even outwardly, an inequality or uncertainty in the incidence of our laws.

Annotations.

"Ne quid nimis."

LORD MAYOR'S DAY.

As we have already pointed out the retiring Lord Mayor is entitled to the thanks of our profession and will always be remembered as the first Chief Magistrate of the City of London to whom occurred the happy and graceful idea of honouring "Medicine" by entertaining at a banquet at the Mansion House many of its representative members. We may now in "speeding the parting" Lord Mayor offer our congratulations to Sir Horatio Davies on the well-deserved honour which has been conferred upon him by Her Majesty and also upon his very successful year of office, in carrying out the duties of which he appears to have given every satisfaction to his fellow citizens. We have now to "welcome the coming" Lord Mayor, and in so doing are glad to claim him as a comrade in a crusade which was initiated by the Founder of THE LANCET many years ago—a crusade in which, alas, we are not able yet to lay aside our armour, for the battle of the purity of the food of the people is not completely won. Both the Recorder and the Lord Chief Justice at the reception at the Law Courts alluded to Sir John Voce Moore's services in connexion with the prevention of adulteration of food. We, too, thank him for those services and respectfully offer him our good wishes, feeling assured that his tenure of the distinguished office to which he has been elected will be a useful, as we trust it will be a pleasant, one. Another word of congratulation on the occasion of the commencement of a new civic year we may perhaps add, and that we proffer to Lieutenant-Colonel Probyn, one of the present sheriffs, who represents on the London County Council that busy division, the Strand, in which our own labours are carried on. Moreover, the firm of which he is, we believe, the head is one which has dealings with the medical profession, and we feel confident that in his future career, actively associated as he is with the two great municipal bodies of the metropolis, we may count upon his assistance and coöperation in all useful measures of sanitary reform.

IS ETHERION A NEWLY-DISCOVERED ELEMENT?

IN our issue of August 27th we alluded to the alleged discovery announced at a meeting of the American Association of Science of an exceedingly attenuated gas to which had been given the name of "etherion." The gas was said to invade all interstellar space and it was even hoped that it would prove to be the "ether" to the undulations of which alone can many physical phenomena be ascribed. "Etherion" was found in the atmosphere and its density was said to be one-thousandth of that of hydrogen. This and other data afforded chemists a shadow of a hope that they were nearing the discovery or possibly even the isolation of Crookes's "protyle," the primordial element. No one could have been more keenly interested in the announcement than Sir William Crookes himself, who is the author of the word "protyle," which he first employed, we believed, in his masterly essay on the Genesis of the Elements. Sir William Crookes speaks with peculiar authority on alleged new elements and his opinion on the subject therefore must always gain a respectful hearing. His latest reflections based upon his fascinating investigations on "Repulsion resulting from Radiation" in 1873, 1876, 1878, and 1880 tend to lead him to the opinion that the supposed new gas may be nothing more than aqueous vapour, highly attenuated water, so to speak! On the evidence at present available—and the complete evidence, we may remark, is not yet to hand—Sir William Crookes considers it more probable that etherion is water vapour than that it is a new elementary gas, and this is corroborated by the observations made by Mr. Brush, the discoverer, that etherion is absorbed by phosphoric acid and soda-lime, as well as by the powdered glass from which it has previously been driven off by heat. Some have been led to hope that the alleged new element might turn out to be the *materia prima*, but, after all, it appears to be merely water. It is curious that water has once more appeared as an element even when critically examined by the most searching methods which the enormous progress of scientific work during recent years has provided. Aristotle at any rate had no such means at his disposal when he regarded the universe as composed of four elements, earth, air, fire, and water. The last in the scale, nevertheless, has apparently evinced such subtle phenomena as to have led an investigator in this year of grace 1898 to conclude that it was a new element—indeed, the *materia prima*—the protyle out of which all the rest in process of time were elaborated, thus bringing forcibly to the front again Prout's classical hypothesis that the elements were formed from one primary matter by various condensations.

THE PAY OF COLLIERY SURGEONS.

A MOVEMENT has been started among colliery surgeons and other practitioners who undertake duties by contract among the working classes of the county of Durham to obtain a higher scale of remuneration, and no one who looks at the matter with an unprejudiced eye and from all points of view can doubt that these members of our profession have right on their side. At present the colliery surgeon receives a fortnightly subscription of 6*d*. from each collier, which sum entitles the subscriber, his wife, and his family (however numerous) to attendance and medicine. This is the rate of pay that has been in vogue for many years, and no doubt when it was agreed upon between the men and their medical advisers it was felt to be a just arrangement. But different conditions now prevail. The wages of the colliers have gone up very much while their expenses have not increased proportionally and in some directions have actually diminished. On the other hand, while the pay of the medical men remains stationary their expenses have greatly increased. Not only do medical men share in the increased burden of taxation now borne by the middle and lower middle classes, but medical education is, by reason of its length and the arduous nature of its pursuit, a more costly affair than it was in times but recently gone by. Again, many of the drugs that now as a matter of routine find places in the medical man's armamentarium cannot possibly be procured at a cheap rate, while the dressings required by antiseptic surgery, not to mention all the modern developments of preventive therapy, make fresh inroads on his depleted purse. Lastly, the necessity that is now put upon the practitioner to employ only fully-qualified men as his assistants—a necessity which in spite of its hard bearing upon many men we are bound to recognise—has practically doubled the amount which the colliery surgeon must pay in salaries, for no man can discharge his duties as medical officer to a large colliery or manufacturing works single-handed. In view of these facts there can be but one opinion—the colliery surgeons have a right to better pay. We believe that in some isolated districts practitioners are receiving 9*d*. per fortnight from each adult workman, and this is the rate of pay which a combined effort is now being made to obtain for all the Durham medical men conducting practices of this character.

Digitized by Google

A circular has been issued to all Durham practitioners to ascertain how far their feelings are in accord in the matter, and if a substantial majority approves a formal notification of their intentions will be sent to the men. We can see nothing but justice in the demand of the medical men for adequate payment, while there is no way of obtaining the desired reform save by combination.

DEATH UNDER OPERATION WHEN ETHER WAS ADMINISTERED.

THE lamented death of Miss Mabel Webb, M.B. Lond., of whom we published an obituary notice last week, whilst undergoing an operation for the relief of a perforation of a gastric ulcer offers some special points for remark. We understand from Dr. Pidcock, the lady's medical adviser, to whom we are indebted for some notes of the sad occurrence, that Miss Webb returned home from her hospital duties on Oct. 27th complaining of being ill. Her condition was diagnosed as being due to gastric ulcer with perforation causing peritonitis, and on the following day Mrs. Scharlieb, M.D., M.S. Lond., saw her and operated. Ether was given in very small quantity and taken well. After ten minutes, during which the operation was being performed, and when, indeed, it was nearly completed, fatal syncope occurred. The death appears to have arisen from collapse—the danger in such desperate conditions—and in spite of the ether. It is important to emphasise this, as study of most of the cases imputed to ether reveals that death was due to the collapsed state of the patient and not to the anæsthetic. It is more general than formerly to employ ether in these desperate conditions, and so it is not surprising that the death-rate under this anæsthetic has apparently increased within the last few years.

THE CASE OF DR. J. A. CAMPBELL.

THE trial of Dr. J. A. Campbell, the late superintendent of the Carlisle Lunatic Asylum, on a charge of criminal assault on a female patient, has resulted in a verdict of "Guilty, but insane." The gruesome circumstances of Dr. Campbell's crime need no repetition in our columns. It is sufficient to say that the evidence against him was complete and overwhelming. On the other hand, the evidence of his mental impairment was just as strong. Mr. Norman, the medical superintendent of Richmond Asylum, Dublin; Dr. Clouston, of the Mornington Asylum, Edinburgh; Sir John Batty Tuke, Dr. Rayner, and Dr. Yellowlees, of the Glasgow Royal Asylum, all testified to the unfortunate man's irresponsibility. The judge, in summing up, commented on the fact that Dr. Campbell, according to the evidence, showed signs of insanity months before the act, in spite of which he was allowed to go on in his position superintending the asylum. No one who has seen much of Dr. Campbell of late years when he was away from his asylum work will be surprised that he has landed himself in serious trouble. Drink cannot be indulged in without some amount of deterioration of brain and of mental capacity and the earliest breaking down is sure to take place in those higher controlling centres which enable a man when at his best to subordinate his passions and those grosser weaknesses which, when they become actively dominant, prove that he is not in his right or normal mind. The eminent authorities who gave evidence of Dr. Campbell's insane condition of mind are above suspicion of swearing beyond the mark even to assist an old fellow-worker in his hour of trouble, and there can be no doubt that his criminal act was the outcome of a brain deranged by persistent alcoholism. Indeed, to us it would appear that the act itself, committed upon such a person and in such surroundings, was characterised by an indiscriminate vigour that points not to mere intoxication or alcoholism but to an active wave of diseased mental aberration. There are those possibly who without looking closely into the circumstances of the case may say that Dr. Campbell was fortunate in being found insane, yet these would have been among the first to have declared that an imprisonment for two years would, when all considerations were taken into account, have been a wrongful sentence. Few, indeed, will envy his enforced seclusion as a criminal lunatic. The case is not without its lessons and its warnings to those who give themselves to drink. The legislature were well advised when they made fornication or attempted fornication on the part of an asylum official or servant with a female inmate a statutory offence and one liable to condign punishment.

A JEW'S OBJECTION TO SERVE ON A CORONER'S JURY.

ON Nov. 4th, at Cheetham, Manchester, Mr. Frederick Shires, who had been summoned to serve at the city coroner's court, asked to be relieved of the duty on Scriptural grounds. The Bible, he said, told him he was not to be in the same apartment as a dead body. He had never been in a house where there had been a dead body, and he did not intend to go into one. He handed a letter from Dr. Salomon which, he said, contained proof that he was a son of Aaron. The coroner was very persistent in his objection to such a reading of the Scripture, especially of Leviticus, 21st chapter and 1st verse, and maintained that the objection was only to touching the dead, whichwas not required in a juryman. But he was no match for Mr. Shires in the quality of persistency, and in the end he did not require him to view the body and discharged him. We cannot help feeling regret that Mr. Shires did not strain a point and discharge his duty as a citizen. None of us like contact with the dead and we should all be glad to evade the duty. But it is imposed upon us in the nature of things and we should accept it and cleanse ourselves as best we can. The Jewish religion itself did not allow contact with the dead to exempt from certain duties and to its credit it provided means of cleansing. In a country where the Jews properly enjoy perfect freedom and protection they should take their share in discharging the duties imposed on all citizens by law. We are much mistaken if all who claim to trace their descent from Aaron would take such an impracticable position as that which Mr. Shires assumed.

THE ISLINGTON MEDICAL CHARITIES.

THE parish of Islington has the largest population of any parish in the United Kingdom. An inquiry into its medical charities cannot fail to be interesting at this time of day when the whole system of medical charity is being criticised from all points of view. Such an inquiry has just been made by a fairly representative committee with Mr. G. T. Keele, M.R.C.S. Eng., as its honorary secretary. The committee was nominated by the Islington Ruri-Decanal Conference in November last. For some twelve months it has held a series of inquiries into the working of the various institutions for dealing with the sickness of that portion of the population which cannot command the attendance of private practitioners on ordinary terms. The amount of information and suggestion in this report is very surprising. We shall probably not be far from the truth in assigning the principal credit of this mine of information to Mr. Keele, whose interest in these questions is of long duration. The report needs to be studied as a whole. The main conclusions of it are that there is no need for any more hospital charities but that the existing charities need and deserve support. Many persons think that with the increase in wages of the working classes and the appearance of cheap dispensaries at which all ailments from corns to

Digitized by Google

convulsions can be prescribed for at 6*d.* a head, all existing and old-fashioned charities may be allowed to die out. The report shows that they are threatened with death by inanition and that society is not feeling the responsibility for their existence which it did a generation ago, but a careful reader of this report and of the conclusions of the committee of the Ruri-Decanal Conference will pause before deciding to starve all such institutions. In London, at least, where rent represents so large a proportion of expenditure and the struggle for life is so keen, there seems still a place for the work of the Dispensary and the Medical Mission. Some suggestions of the report, such as payment of the honorary staffs of hospitals, larger payments by patients, additional collections from churches and even vestries, would require much consideration and qualification to receive our approval. There is a tendency to throw upon overburdened churches and over-rated parishes duties which comfortable citizens should discharge in their own private capacity. A consideration of all the misery which is implied in the work of institutions as detailed in this report will convince such citizens of their responsibility. The corresponding obligation of the institutions not to abuse charity is not overlooked and due credit is given to the Great Northern Central Hospital for rules intended to exclude unfit patients.

PRIMARY MALIGNANT DISEASE OF THE SUPRARENAL BODIES.

IN the *American Journal of the Medical Sciences* for October Dr. H. D. Rolleston and Mr. H. W. J. Marks have published an exhaustive paper on this subject, based on 6 cases which occurred in St. George's Hospital and which they examined microscopically, and 20 collected from literature or obtained from other sources. In order to be quite certain of malignancy they include only cases where there were secondary growths or where there was invasion of adjacent parts, and probably excluded some genuine cases. The incidence in both sexes was exactly equal. The average age was 37½ years; the extremes were 9 months and 73 years. Dr. Rolleston and Mr. Marks remark that it is almost impossible to differentiate histologically an adenoma disorganised by hæmorrhage from a primary malignant growth. Hence they prefer to rely for diagnosis of malignancy on metastasis and invasion of adjacent parts and not on the microscope—a noteworthy fact. In the 26 cases the liver was the seat of secondary growths in 14, the lungs in 6, the bronchial glands in 2, the pleura in 3, the kidneys in 3 (they were also invaded by continuity in 4), the aortic lymphatic glands in 6, and the peritoneum in 3; the heart, cerebrum, cerebellum, bones, and skin each in 1; the other adrenal in 2 (it was also invaded by continuity in other cases). It is difficult to prove, but it has been asserted that both suprarenals were simultaneously affected by primary growths in 2 cases. In 24 cases the nature of the growth is stated: 15 were sarcomata and 9 carcinomata. Suprarenal tumours are soft and vascular and have a tendency to soften in their interior with the formation of a central cavity. The symptoms of Addison's disease in a characteristic form are never induced because the disease proves fatal too soon; but some of the symptoms may occur. Pigmentation of the skin is rarely observed. Vomiting was a marked symptom in some cases. Asthenia was very notable in some cases, but not perhaps more marked than in malignant disease elsewhere. Pain in the back may occur. Dyspnœa may result from pressure on the diaphragm. Œdema of the legs was present in 5 out of the 6 cases observed in St. George's Hospital. In one case pressure on the lumbar plexus caused pains in the left leg. There was also irregular temperature which, as Butlin and Colby have shown, with regard to sarcoma (St. Bartholomew's Hospital Reports, 1895) is not unusual in patients with rapidly growing malignant tumours. Excessive development of hair has been occasionally noted, emaciation is often marked, but in the case of a child, aged three years, the weight was 44 lb.—much in excess of the normal. As to diagnosis, though of considerable size the tumour may from its soft and cystic character entirely escape detection during life, and the symptoms may merely suggest deep-seated malignant disease, latent gastric cancer, or aneurysm. Again, secondary growths in the liver may produce enlargement and give rise to a diagnosis merely of malignant disease of that organ. Peritoneal effusion which may be sanguineous occurs in some cases. If felt the growths are from softening liable to resemble cysts in contrast to renal tumours which are solid and readily palpable. The prognosis is hopeless unless the growth is removed—a more difficult operation than for renal tumours. Mr. H. Morris successfully removed a suprarenal growth, but secondary tumours existed in the liver at the time of operation.

A DEFENCE OF THE MIDWIFE.

DR. THOMAS J. HILLIS of New York lately read a paper at the meeting of the New York County Medical Association which is reported in full in the *Medical Record* of Oct. 1st. The paper was entitled: "Some Remarks on the Midwifery Question—Must the Midwife Perish?" The writer dwelt with eloquence on the past history of the midwife in all countries and stages of civilisation, and with much reverence for antiquity argued that she should be spared—that her abolition would be the ruin of the general practitioner and the triumph of the lady doctor. He maintained that on the whole she is the friend of the general practitioner and sends for him whenever a difficulty arises or a fee has to be obtained. He denies that the mortality is excessive under her gentle and unpretentious rule. He evidently thinks that there is a very peculiar Providence over midwives and their work. "Nature is kind to the puerperal woman in her simple and lowly condition, especially when surrounded by squalor and filth." He draws a vivid picture of the difference between her quiet and homely ways and the ostentatious style of the young disciples of Æsculapius who, with their large and much-containing obstetric bag, invade the households of the parturient women in numbers and for days together before the event comes off, "making about 300 examinations each" with disastrous results, of course. He tells us that half the obstetric work of New York is done by women, most of whom are ordinary midwives, and a small fraction are women doctors; the remainder, a goodly portion, is accomplished through the good offices of neighbours and janitresses, which latter often take the place of first assistants to the historic and much-abused midwife. Dr. Hillis asks us to take a kindly view of the midwife. He certainly is "to her faults a little blind and to her virtues very kind." He insists on her cheapness and on the impossibility of the State preventing lying-in women from having such attendants if they please to have them, all which is too clear to us who have had very recent experience of the limited power of the State to enforce legislation for the promotion of health against the will of the people. But he carries his apology for midwives too far and is correspondingly unjust to medical teachers and students, who, at least in this country, are more careful than at any previous time to do the most good and the least amount of harm to mother and child. In a letter by Mrs. Elizabeth Jarrett, M.D., criticising Dr. Hillis's paper, the writer argues, with very doubtful truth, that women prefer to be attended by women. But she incidentally mentions that "the city of New York is taking care to protect its poor

Digitized by Google

by paying a proper fee to such institutions as will guarantee to send a reputable physician to attend poor women in their confinements." This is an interesting fact, worth the consideration of those amongst us who wish to improve the chances of lying-in women. No Midwives Bill which we have yet seen contains any provision for ensuring that in every serious case a lying-in woman, however poor, shall have the benefit of qualified medical attendance, and without such provision no Midwives Bill should pass.

THE PUBLIC SCHOOLS AND HOSPITAL STAMPS.

BOYS are all fond of the Prince of Wales and will be very apt to do anything which he asks them to do. He appealed in the early part of the year to the public schools to help him in connexion with his Hospital Fund. The sixth forms and the head-masters have coöperated in circulating the appeal, and already lectures have been delivered on the work of the London Hospitals in the following schools: Epsom College, Marlborough, Shrewsbury, Wellington, and Cheltenham. Hopes are entertained that as the movement spreads, permanent small subscriptions will come from the great public schools to the London hospitals.

THE INQUEST ON THE LATE MR. HAROLD FREDERIC.

THE proceedings at the inquiry before Mr. W. P. Morrison, coroner for the Croydon district, into the cause of the death of the late Mr. Harold Frederic, the well-known author and journalist, terminated on Wednesday last in a verdict of "Manslaughter" against Miss Kate Lyon, a young woman with whom the deceased cohabited, and Mrs. Mills, a Christian Scientist. The verdict registered the opinion of the coroner's jury that Mr. Harold Frederic was influenced by Lyon and Mills when in a state of physical and mental helplessness to his detriment, so that he neglected to take medical advice, with the result that his death was accelerated. The two women were arrested later and released on bail.

DEATHS UNDER ANÆSTHETICS.

THE following particulars of a death under chloroform have reached us. The patient, a child, aged six years, suffered from malignant disease of the jaw. She had three teeth removed at the Birmingham Dental Hospital and was there advised to go to the General Hospital for removal of a portion of the jaw. It was, however, eventually undertaken in a private house and chloroform was administered by a medical man, the "open" method being employed. Mr. Newton, the surgeon in charge of the case, proceeded to remove three teeth and was about to resect a portion of the jaw when the child stopped breathing and eventually died from asphyxia due to the anæsthetic. The death appears to have followed an overdose, the method being one which only too easily leads to such an occurrence. A death occurred recently at St. Mary's Hospital which, although it appears to have been in no sense a death due to ether, yet demands some notice, since it illustrates how deaths "under" an anæsthetic are frequently not "from" the anæsthetic. The patient, a man, aged fifty-one years, described as not being strong, fell some 20 feet into an area and sustained severe injury. He was seen at a hospital and offered admission. This he declined. After treatment at home his medical adviser called into consultation a surgeon from another hospital, who found the man in a most exhausted condition from abdominal distension. This distension had pressed upon and hampered the heart. It was decided that the only chance for the man lay in an abdominal section, and with a view to this he was removed to the hospital and given a small quantity of ether. He was at this time practically moribund, being almost pulseless. While being conveyed to the operating-theatre his pulse ceased and vomiting occurred and the respiration grew laboured, finally ceasing. A post-mortem examination revealed, besides great distension of the abdomen, bruising of the mesenteries. The lungs were œdematous, but they and the upper air-passages were entirely devoid of vomited matter and admitted air freely. There was splintering of the body of the fifth dorsal vertebra, but no injury to the spinal cord except possibly slight compression. The death was syncopal in character and was in no way due directly or indirectly to the small quantity of ether which had been inhaled. We are indebted to Mr. C. H. Straton, house surgeon at St. Mary's Hospital, for particulars of this case. The peculiar danger of cases of distension of the intestines from the point of view of the anæsthetist is the risk of vomiting and the entrance of vomitus into the air-passages. Although vomiting took place in this case the care exercised appears to have prevented this danger. The exhausted state of the patient contra-indicated lavage before giving the anæsthetic or such a procedure would have been advisable. In manipulation of the intestines during operation "reversed peristalsis," so liable to occur, causes regurgitation of intestinal contents into the stomach and induces vomiting. In many instances this has caused death through the vomitus being sucked into the lungs.

CRUSHING OF THE CERVICAL SPINAL CORD: PROLONGATION OF LIFE FOR THREE AND A HALF HOURS BY ARTIFICIAL RESPIRATION.

IN the *Medical Chronicle* for September Mr. J. W. Smith and Dr. J. G. Clegg have published the following case. A cab-driver fell from his box and was admitted to the Manchester Royal Infirmary four minutes later. He was unconscious and his face was livid. Respiration had stopped and the radial pulse was absent, but the heart was beating feebly. Artificial respiration was performed; in ten minutes the lividity disappeared and the pulse became full and strong. When artificial respiration was stopped there was no attempt at natural breathing; the face became cyanosed and the pulse failed. He recovered consciousness and could mutter a few words. Motion and sensation were normal in the face, absent below the neck. If artificial respiration were now stopped an attempt at respiration—spasmodic depression of the lower jaw and angle of the mouth, dilatation of the nares, and protrusion of the tongue—took place. There was abnormal mobility of the head with crepitus, and a hard prominence could be felt in the mouth pressing forward the soft palate. After 2½ hours the general condition was worse and the thorax gradually became rigid, making artificial respiration difficult and finally impossible. He died at the end of 3½ hours. At the necropsy the odontoid process and upper third of the body of the axis were found separated, the atlas was fractured in three places, and the cord was almost completely divided. Mr. Smith and Dr. Clegg have been unable to find any other case of spinal injury in which life was thus prolonged by artificial respiration.

AN ITALIAN CRITIC ON "OPTIONAL VACCINATION."

IF there is a prominent journal in Europe which might be supposed to make "liberty of the subject", supreme, even in matters affecting the public health, it is the *Secolo* of Milan. This very advanced organ, in touch, nay, in active sympathy, with the most uncompromising radicalism, comments in a tone of "pained surprise" (*dolorosa sorpresa*) on the Vaccination Bill which in August last became the law of the land

Digitized by Google

in England. Considering the authority justly exercised by British practice and British precedent in the hygienic sphere it deplores the enactment as not only disastrous for the community it immediately affects but as supplying an all too welcome weapon for the *laissez-faire* policy which, extended to sanitation, has proved so calamitous in Italy. "Facts, however, are stronger" (it continues) "than the affirmations and the votes even of a British Parliament," and it cites from the statistics of Dr. Ramella, medical adviser in chief to the Turin municipality, most overwhelming evidence as to the benefits which vaccination and revaccination have wrought for Italy in the last decade. Dr. Abba, director of the Municipal Laboratory of Bacteriology, also in Turin, contributes corroborative testimony, and, going further afield than Italy or the European continent, adduces the experience of Buenos Ayres and holds it to be "crucial" in favour of Jenner's discovery. Quoting with entire approval the rescript of the Royal College of Physicians of London as adding an authoritative imprimatur to the views held by all sound sanitarians throughout Christendom the Milanese organ reproduces textually the statement of Dr. Vallin, the distinguished French hygienist: "In France the healing art as a whole, and her scientific bodies generally, have not ceased for the last twenty years to insist on compulsory vaccination;" and it concludes: "And we in Italy who have had such vaccination for ten years, and for ten years have been able to attest its good results, are now to be told that vaccination is useless where it is not mischievous. Fortunately with us the abolitionists are apostles without followers and without credit."

PSEUDO-HYPERTROPHIC PARALYSIS.

FOR once in a way we make an exception to our general rule and answer a layman on a question of medical treatment. The following letter is our excuse: "I have a little boy, aged ten years, suffering from hypertrophy (mock paralysis). Up to nine years of age he was still able to walk a certain distance, although in his gait he waddled somewhat from infancy. He has been under electric treatment for eight months in a hospital, but has returned home so much worse that he cannot stand or walk. ..... I should be most thankful if you could advise or suggest in such a case anything that could be done for him." It is evident that our correspondent's letter refers to a condition of pseudo-hypertrophic paralysis, in such a case as is described probably one of the most hopeless of maladies. It is true that with the wider experience of this disease which recent years have brought we are justified in regarding it more hopefully in many cases. The disease was formerly regarded as inevitably progressive. Now it is recognised that in many cases after a certain stage is reached it ceases to progress and a patient may even improve a little. But before this stage is reached it usually happens that a condition of greater or less helplessness has been established. Unfortunately medical treatment seems to have little if any effect in modifying the progress of the malady. Electrical treatment, massage, passive and active gymnastic exercises have all been tried, but so far as we are aware without any striking result. The usual nerve tonics, strychnia, arsenic, &c., have also been used, and no doubt their influence is in the right direction. Unfortunately it seems as if the cases in which the malady begins in early life and rapidly attains a degree in which it disables the patients are the worst in regard to any hope of improvement in the power of locomotion. But the general health often remains good and the condition is at least one which is unassociated with physical pain. Our correspondent may feel sure that from the staff at the hospital at which the patient has been under

Digitized by Google

the raised portion of bone can be easily laid down with the scalp flap when the wound is being closed. In agreement with the most general practice nowadays in these operations Dr. O'Neill never drains unless it is absolutely necessary. When the wound has been dressed it is not disturbed for at least a week unless the temperature exceeds 100° F. or the patient complains of severe pain and restlessness. In order to illustrate the practical results of this treatment 4 cases were quoted in which patients with very severe injuries to the head were dealt with by these methods and the patients themselves were exhibited to the meeting. In one case marked dementia had appeared after a fall from a height of 12 ft. on to the head, but three or four days after trephining on the site of a fissured fracture of the skull the mental symptoms entirely subsided. This case is illustrative of the best modern treatment, for even if no fracture be discernible an exploratory examination of the contents of the skull is fully justified if marked functional derangements succeed the primary effects of intracranial injury.

ON Sunday afternoon, Nov. 20th, Dr. E. Baxter Forman, J.P., L.C.C., will lecture at the South Place Institute, South-place, London, E.C., on "Medical London," with lantern illustrations, being the sixth of a course of Sunday Afternoon Free Lectures on "Our Cities and Municipalities."

THE annual meeting of the Fellows and Members of the Royal College of Surgeons of England will be held on Thursday, Nov. 17th, at 3 P.M., as has already been announced in our columns.

THE Roentgen Society will hold a conversazione at St. Martin's Town Hall on Monday evening, Nov. 21st, from 8.30 to 12, at which there will be music and demonstrations of x rays.

PROFESSOR WILLIAM MACEWEN, M.D., LL.D. Glasg., has been elected a corresponding member of the Medical Academy of Rome.

THE ROYAL COMMISSION ON THE METROPOLITAN WATER-SUPPLY.

THE thirty-second sitting of the Royal Commissioners was held at the Guildhall, Westminster, on Monday, Nov. 7th. The Commissioners present were Lord Llandaff (chairman), the Right Hon. John William Mellor, Q.C., Sir John Dorington, M.P., Sir George Barclay Bruce, Mr. de Bock Porter, Major-General Scott, and Mr. Robert Lewis.

At the commencement of the proceedings the CHAIRMAN said that he proposed to deal first with one small subject of the inquiry—the intercommunication between the mains of the different water companies. The President of the Local Government Board had asked the Commissioners to report upon that subject as soon as possible with a view to immediate legislation.

Mr. POPE, Q.C., on behalf of the water companies, said that they had considered their position with regard to this question and were prepared to offer evidence as to the practicability of an interchange of water between the companies. The question, however, involved so many considerations of detail that it seemed best to them to save the time of the Commission by dealing with the general question rather than to go into great detail with regard to any particular scheme of connexion. The companies had come to the conclusion that the intercommunication between them would be convenient, and they therefore proposed to promote next session a Bill dealing with the matter. At the present time the companies had not the statutory power to undertake work for any purpose beyond their authorised districts of supply, and there were special obligations which bound individual companies not to supply

Digitized by Google

water beyond their authorised areas. On behalf of the associated water companies he wished to call the attention of the Commissioners to a series of resolutions which expressed in general terms their views with regard to the contemplated legislation. Briefly, the scheme of intercommunication was practicable, but it was desirable that some authority should be armed with the necessary power to say in what way the connexions should be made, not only in the case of an emergency but at any other time, and they suggested that matters of detail should be left to the Local Government Board to decide, and that the companies should be placed under an obligation to carry out decisions on the subject given by that Board.

The CHAIRMAN pointed out that they had been asked to advise not only whether it was practicable to connect the different systems of supply, but if so by whom and in what proportion the cost should be borne, and what new legal powers were necessary to give effect to such an arrangement.

Mr. POPE said that these matters had been considered by the companies and that they had agreed to introduce a bill dealing with the matter. The provisions of the bill which the companies proposed to submit were, *inter alia*, to the following effect:—

1. The companies forthwith to consider what works are required for the above objects and to submit proposals to the Local Government Board for approval. The Local Government Board to be empowered to approve and authorise such works with or without modifications or to authorise and order other works for the like objects.
2. Further works for the above objects may in like manner be from time to time authorised and ordered if and when required.
3. The respective companies to carry out in their respective districts all works so authorised.
4. The Local Government Board to be empowered to authorise the supply of surplus water from the works of any company to the works of any other company for the time being requiring the same and the Local Government Board to have power in case of emergency to authorise any of the companies to take more water from the Thames than they are now authorised to take.
5. All expenditure of the respective companies in relation to any such works to be deemed capital expenditure and for the purpose of meeting such expenditure the Local Government Board to be empowered from time to time to authorise the respective companies to issue an additional amount of debenture stock.
6. No contribution to any sinking fund to be made in respect of capital issued for the foregoing objects.
7. Subject to reasonable contribution by any company taking and utilising by means of the proposed works and powers water which it would not otherwise have been enabled to take and utilise, the interest on debenture stock applied by the respective companies for the foregoing works to be borne by the eight companies in proportion to their respective water rentals.
8. Any company taking water from another company to pay for such water to the company supplying it at a rate to be agreed upon or fixed by arbitration.
9. A standing arbitrator to be appointed by the eight companies or failing such appointment by the Local Government Board, and in case the respective companies do not agree amongst themselves such arbitrator at the end of each year to decide as to the contribution of either company taking and utilising the water rendered available by the proposed works and also to decide any matters in difference between the companies.

The CHAIRMAN pointed out that the proposed legislation was designed to give novel powers to the companies. In the first place they were to be allowed to draw water from the Thames under new regulations; in the second place, there was no provision for a sinking fund; and, thirdly, the Local Government Board was authorised to arrange for the raising of capital for an emergency.

Mr. POPE said that the extra amount of water from the Thames was only allowed to be taken in cases of emergency, that the expenditure in carrying out the connexions between the mains might rightly be deemed capital expenditure, and that it was proposed to appoint an arbitrator to decide any questions of detail with regard to the issue of additional debenture stocks.

Mr. ERNEST COLLINS, one of the engineers to the New River Company, was examined by the Chairman with regard to the question as to whether it was practicable from an engineering point of view to connect the different systems of supply in the case of all the existing water companies. The witness admitted that at the present time in periods of drought hardly any of the companies had water to spare.

The CHAIRMAN asked in that case what was the use of intercommunication and the witness replied that that point had been considered in drawing up the scheme, and that the engineers of the companies had received instructions in the autumn of last year to consider the real practicability of the scheme. At that time they found that the Chelsea Company was the only one that had any surplus water at times of the greatest pressure. The Chelsea Company was authorised to draw from 8,000,000 to 10,000,000 gallons every day from the Thames in excess of the amount which they really required for the supply of their district. At the time of pressure the other companies had sufficient for their own supply but none to spare That fact seemed to the witness to strike at the root of the desirability of intercommunication. Intercommunication was useless if there was nothing to communicate.

Mr. POPE pointed out that since the time at which the engineers consulted on the matter (September, 1897), the Southwark and Vauxhall Company had obtained additional powers to abstract water from the Thames. The witness said that their report of 1897 had been drawn up with a view to providing for the accidental breakdown of a pumping engine, the fracture of a main, or a temporary disablement of the works. It would not provide for any great failure of supply such as that which had taken place in East London during last summer. At the present time the Southwark and Vauxhall Company were authorised to take about 10,000,000 gallons daily in addition to the quantity which they required for carrying out their present supply, and the Chelsea Company had a surplus of 8,000,000 to 10,000,000 gallons.

In answer to the CHAIRMAN the witness said that he did not consider the report which the engineeers had drawn up in 1897 was the best mode of giving intercommunication, and in answer to Mr. DE BOCK PORTER he said that the experience of the past year had led the engineers to modify the proposal originally made. He thought that with the exception of the East London Water Company the other companies were capable of taking care of themselves.

In answer to the CHAIRMAN the witness said that he had a better scheme than that which the engineers had originally suggested, but that he was not authorised to say that it had been approved by the boards of directors of the water companies. A permanent scheme such as the one he had in view would require a considerable outlay. The cost of the original scheme on which, as the Chairman suggested, he now threw cold water, amounted to something over £307,000, and that scheme was practically only wanted for the use of the East London Waterworks Company. The original scheme, however, would not be sufficient to make good the effects of a drought like that experienced last summer; it would be sufficient only to overcome some temporary breakdown in the machinery and mains. The scheme which the witness suggested as being the best was to make use of the station at Battersea which belongs to the Southwark and Vauxhall Waterworks Company. He suggested that that company instead of giving up this station as at present proposed should make an arrangement by which it might be utilised by all the water companies. A description of this station has already been given in THE LANCET; it contains reservoirs, filter beds, and pumping engines. According to Mr. Collins's scheme water would be filtered at this station and pumped in different directions by mains specially laid to convey it. The first main would go from Battersea to Campden-hill to the reservoirs of West Middlesex and Grand Junction Companies. The second main would pass from Campden-hill to New River Head. The third main would go from Battersea to Claremont-square, another New River station. The fourth main from Battersea to the Brixton station of the Lambeth Company and the fifth from Battersea to the Nunhead station of the Vauxhall and Southwark Company. With regard to the cost of this scheme the witness suggested that the value of the Battersea station for building purposes was about £10,000 an acre and that it contained 30 acres. The Southwark and Vauxhall Company had sold part of the land and it was arranged that the station should be given up. The new proposal, therefore, was that the Battersea station should be continued in working order and that new mains should be laid down in the directions suggested. In addition to this, to complete the scheme it would ultimately be necessary to lay another main from the Thames intake to the Battersea station to convey the unfiltered water, for the main at present used for that purpose will ultimately be required for the distribution of water by the Southwark and Vauxhall Company for the supply of their own customers. The work of laying mains from Battersea to the reservoirs of the different companies would take about eight months to carry out.

The CHAIRMAN asked who should pay for it, and the witness said that he could give no help with regard to the solution of that problem.

Mr. RESTLER, engineer to the Southwark and Vauxhall Company, described the Battersea station of that company at

Digitized by Google

Battersea, giving some information which has already been published in THE LANCET in the description of these works. He said that in his view the scheme which had been propounded by Mr. Collins was in every way superior to that which had previously been advised by the engineers of the companies.

Mr. W. H. BRYAN, engineer to the East London Waterworks Company, in answer to the Chairman said that he had that morning received a letter asking him to give details as to what connexions it would be necessary to make in order that his company should be able to ensure the proper supply of water next year in case there should be a drought similar to that which has obtained during the present year. The witness said that since the morning he had been unable to go into the details which he had been asked to give and that he would be prepared to give the necessary evidence next week. In answer to Major-General SCOTT Mr. Bryan said that he thought that if the work were vigorously proceeded with the works mentioned by Mr. Collins could be completed by the end of next summer, but it would be impossible to finish it if they had to wait for an Act of Parliament for its authorisation. At the present time the East London Waterworks Company were receiving 5,000,000 gallons of water daily from the Southwark and Vauxhall Company, 200,000 gallons from the Kent Company, and 8,000,000 gallons from the West Middlesex, Grand Junction, and New River Companies.

Mr. JOHN HOLLAMS, legal adviser to the Associated Water Companies, gave it as his opinion that it was impossible to formulate any definite permanent scheme of intercommunication. The plan must vary from time to time as population increased or circumstances changed. It would be better, therefore, if the companies under the control of the Local Government Board were to be empowered to meet emergencies as they arose. In the opinion of the waterworks companies, including, he believed, the East London Company, the proposed works were unnecessary, yet the companies were prepared to carry them out to guard against difficulties in the event of some unlooked-for event.

The thirty-third sitting was held at the Guildhall, Westminster, on Tuesday, Nov. 8th, Lord Llandaff presiding, when Mr. John Hollams concluded his evidence, and the chairman of the Southwark and Vauxhall Company, Sir Henry Knight, emphasised an opinion that there had not been an insufficient supply of water in East London during the summer of 1898. We must delay a detailed report until next week.

"THE RECENT EPIDEMICS OF PLAGUE IN BOMBAY."

A VERY interesting as well as elaborate and carefully considered paper, on this subject was read before the Geographical Society of Manchester in May last by Mr. H. M. Birdwood, C.S.I., LL.D., and has now been issued in the form of a pamphlet. Mr. Birdwood was formerly a Member of Council and one of the judges of Her Majesty's High Court of Judicature at Bombay, and was present during the first epidemic of plague in that city. He is consequently entitled to speak with some authority on the subject, and his legal and official training has enabled him to sift and arrange the facts so as to present us with a very clear and relevant historical record, as well as a concise but correct medical history, of the epidemic. All medical authorities, in the first place, are agreed as to the identity in character of the "bubonic fever" of Bombay with the disease historically known as plague, and also as to the probable identity of the highly infectious pneumonic type of the disease, in which the characteristic glandular enlargements are not always present, with the Black Death of the fourteenth century. In the latter form, of which the recent occurrences at Vienna have furnished a very striking example, the bacillus pestis of Kitasato is present in large quantities in the patient's sputum. That this bacillus is endowed with highly pathogenic properties and is the cause of the disease does not admit of any doubt, for the tragic occurrences of the Vienna outbreak have almost partaken of the nature of a scientific experimental demonstration of it. There are, as we have frequently said, various conditions connected with the life-history of the plague bacillus about which we as yet know little or nothing, such as its habits and manner of life, whether in the soil or in the air or in the bodies of men and the lower animals, the conditions which favour its growth and the development of its poisonous powers, the ways by which it effects an entrance into the body, and the methods by which susceptible individuals, races, and communities may be rendered immune to its attacks. We require also to study the conditions favourable to the rapid growth and diffusion of this micro-organism and the way in which it comports itself when multiplied and aggregated so as to give rise to epidemics. A brief and interesting summary is given in the paper under review of the history of plague and its geographical distribution and the part it has played in the world in past times. The bacteriological researches of modern inquiry have thrown a new and most important light on the subject and given a precision to our studies such as we did not possess hitherto. We are consequently making some real progress in our knowledge in various respects. The great difficulty with which we have to contend in the case of plague and other epidemic diseases is that attending the discovery of their first importation into any given place and the prompt recognition of the cases primarily attacked. The circumstances connected with the importation of plague into Bombay, for example, have not been definitely traced and the disease was, no doubt, actually present and spreading in a densely crowded community for several months before its real character was recognised, and it had consequently had time to take root and to establish itself as an epidemic before official methods for its control could be properly or efficiently applied. Although the measures adopted in India may not have been so successful in stamping out the disease as could have been desired, it is quite a mistake to suppose that they have therefore done no good, for the evidence points the other way. Practically it all depends upon carrying the natives with us if our efforts are to be successful. The Indian Government have taken immense pains and gone to great expense, as well as incurred great opposition, in their attempts to combat the disease.

At Poona, which is a hotbed of disaffection, the efforts which have been made in this direction have been very successful. The whole question of plague requires to be thoroughly gone into with the view not only of finding out its various endemic centres—the geographically independent plague foci for its periodical spread—but the insanitary conditions which favour its development in different localities, as well as the question of the prophylactic safeguards against the disease which can be adopted, in which direction M. Haffkine, for example, has worked with so much scientific zeal and apparent success. We are very glad that a scientific commission has been appointed to investigate and report upon all these points. Meanwhile Mr. Birdwood's paper is well worthy of study.

Telegraphic reports from India show that the plague returns for the week ending Oct. 29th have continued to decline as regards Bombay city, the deaths reported being 96, as compared with 116 in the previous week. Nearly 5000 deaths, however, occurred in the other districts of the Bombay Presidency. The disease continues to increase in Mysore State, 400 deaths being reported from Bangalore, and it shows a tendency to spread. There is a slight decline in the Madras districts, while Upper India is free.

"THE ADMINISTRATIVE CONTROL OF TUBERCULOSIS."

TUBERCULOSIS AND THE CONTROL OF OUR MEAT-SUPPLIES.

SIR RICHARD THORNE, who has chosen the above title for the Harben lectures of this year, delivered the first of a series of three weekly lectures at the Examination Hall of the Conjoint Examining Board, Victoria-embankment, on the 2nd inst. The earlier portion of the lecture was taken up with a review of the action which had been adopted during the last forty-five years in the control and prevention of the different forms of tuberculosis, and of the results achieved, as shown by certain vital statistics which had been specially prepared by Dr. J. F. W. Tatham for the purposes of the Royal Commission on Tuberculosis appointed in 1896.

Digitized by Google

The diminution in the rate of death effected during this period was illustrated by contrasting the period 1891–95 with that of 1851–60, and it was shown that for all forms of tuberculosis collectively the diminution had been constant, that it had applied to all ages, and that at certain age periods it ranged from no less than 30 to over 50 per cent. In the case of phthisis the diminution had been even greater, reaching at certain periods of life a reduction of over 60 per cent. All this had been effected before the discovery of the tubercle bacillus had led to any special action based upon bacteriological knowledge; it had resulted in the saving of hundreds of thousands of lives and, as the lecturer put it, if with the advantage of increased and accurate knowledge as to the causation of tuberculosis as much can be accomplished during the next half century as has been accomplished in the period 1851–95, death from pulmonary tuberculosis at many age periods will then be entirely abolished in this country. This point was urged because the lecturer deemed it so important that the former methods of prevention should not be lost sight of but should still be pressed forward in continuation of a work which had been so eminently successful in the past. These methods were explained at length. They had to do, in the main, with all the administrative measures by which increased movement of air and access of light were secured about and within our dwellings and with those which had led to a lowering of the level of subsoil water in our towns and in the neighbourhood of villages and dwellings.

But in contrast with this great success it was next pointed out that in the case of death from tabes mesenterica the diminution in the rate of death had not only been quite trivial at most ages, but that under one year of age the whole of the advantages from sanitary measures had been lost, and there was in addition an actual increase in the amount of death when the later years of the past half-century were compared with the former ones. This was held to be due to the fact that whilst in the case of phthisis the infection is in the main received aerially it is received by the digestive tract in the case of tabes mesenterica; and it was sought to ascertain what change or changes had taken place during the term of years in question which had turned the gain achieved in the case of the aerial infection into a loss in the case of an infection received by the alimentary tract. The answer was that the explanation was to be found in food supplies—namely, meat and milk.

The remainder of this first lecture was devoted to the question of meat in relation to tuberculosis. The view expressed was that the source of danger from this cause had been overrated by some who demanded measures of considerable stringency, and it was shown that the experiments on which some of these opinions had been based—such as the intentional inoculation of meat used for feeding purposes—were of the nature of laboratory experiments and found little or no parallel in everyday life. So also it was pointed out that the greatest diminution in the rate of tuberculous death had taken place not only at the meat-eating ages, but during a term of years in which there had been an enormous increase in the amount of meat consumed in this country.

The demand for compensation by butchers out of public funds when tuberculous carcasses were seized was next considered, and the lecturer held, for a number of reasons which were set out in detail, that it would be altogether wrong in principle to allow a trader who voluntarily placed an article of food on sale to take the whole profits if the article was sound and to be compensated out of the public funds if it turned out that he had made a bad bargain. The true remedy, it was held, for the control of such danger as existed from eating meat that was tuberculous lay in the abolition of private slaughter-houses and the provision of public ones in which a uniform system of inspection and a uniform standard for condemnation would be observed. This matter of public slaughter-houses was held to be the governing factor in dealing with the risk due to tuberculous meat.

As regards imported carcasses it was maintained that inspection of them should be instituted at the ports of arrival, the expenses of the staff and necessary establishments to be covered by a small tax on each carcass imported.

TUBERCULOSIS AND THE CONTROL OF OUR MILK-SUPPLIES.

The second lecture was delivered on Nov. 9th, on the subject of the administrative control of milk-supplies in relation to tuberculosis in man. Sir Richard Thorne adverted again to the fact that during the last half-century there had been an immense reduction in the death-rate from many forms of tuberculosis, notably of phthisis, in connexion with great sanitary improvements that had been effected, and he recalled the fact that infants and children must, according to all experience, have benefited correspondingly. But when the death-rates from tabes mesenterica, a form of tuberculosis in which the infection is received into the alimentary canal instead of into the lungs were examined, it was found not only that all the gain attained at other ages had been lost in the case of children and infants, but that in addition to this there had been a very heavy increase in deaths from this cause amongst infants under one year of age. The saving of life from tuberculosis in all its forms and from phthisis had been at the rate of from 45 to 66 per cent. at different ages; whereas in the case of infants under one year of age, not only did all this gain disappear in so far as tabes mesenterica was concerned, but there was in addition an actual increase of 21·7 per cent. during the past fifty years. Very similar results had followed as regards tuberculous meningitis; and both these forms of tuberculosis were essentially due to the reception of the tuberculous infection into the alimentary tract. This increase had also gone hand in hand with a steady increase in the consumption of cow's milk as a food in this country; English people being almost the only civilised nation in the world who habitually consumed uncooked milk. He then showed from official returns how large was the amount of tuberculosis amongst milch-cows; and quoting the report of the Royal Commission on which he had served he explained that the artificial conditions under which milk was now produced in cowhouses, which the animals sometimes never left for a single moment during the period they were in milk and which at times reached a whole year, were precisely those most certain to produce that increase of this disease in cows which had been going on. Fortunately the immediate danger to man was limited to the existence of tuberculosis in the cow's udder, but the early stages of this affection were most difficult to detect and it was a form of tuberculosis which tended at times to spread with great rapidity. The danger to man, and especially to the infant population, was one of real gravity, and the loss of child-life due to this disease in milch-cows was appalling. He did not recommend, as some had done, the removal of every tuberculous cow from the dairies and cowsheds, for this, at the lowest estimate, would mean the removal at once of over half a million cows from our milk-supply, but all cows with advanced tuberculosis in any part of the body, and all cows with suspicious disease of the udder, should be at once seized and slaughtered. Amongst the most prominent of remedies was the provision of adequate cubic and floor space in cowsheds so as to ensure proper ventilation; and he showed that this was often more necessary in country than in town cowhouses because the latter are often much more under control than the former. Both in Liverpool and in Manchester the percentage of samples of milk containing tubercle bacilli was far greater in the case of country milk than in that obtained in those cities themselves. He further advised the abandonment of the practice of keeping cows for months with their mouths and nostrils against a wall—a practice which secured for them the least chance possible of breathing fresh moving air, and he advocated frequent and systematic inspection of cowsheds and dairies by expert officials. As regards compensation for animals seized his views were not the same as those which he had expressed against any such payment from public funds in the case of the seizure of tuberculous carcasses voluntarily put on sale by the butcher. In the case of the milch-cow the milk alone was placed on sale, and whilst the use of the milk should be at once stopped, the cow might be perfectly good and of value for feeding purposes to be sold as meat, and whatever value attached to a cow in this sense should be repaid, if the animal was seized and slaughtered, by the local authority. He further maintained, as he did in the case of meat-supplies, that any stringency of control over home supplies in the case of milk should, as far as practical, be also maintained over imported milk and milk products, as, for example, by appointing inspectors at our ports and by chemical and bacteriological examinations of the materials imported; the whole expense to be borne by a small tax on all such articles as are imported. Incidentally he referred to the success attained in the diminution of tuberculosis in cows in Denmark by the aid of the tuberculin test, and finally he most strongly urged that

Digitized by Google

English people should be educated to acquire the habit of cooking their milk before using it. He set aside the ordinary objections raised to this proposal, and he showed that if milk were boiled for a single instant the danger of tuberculosis would be gone, and a cause of thousands of deaths every year amongst children and young adults would be removed. He appealed to the medical profession to use their great influence in thus controlling the present waste of life which followed on the use of uncooked milk.

The third lecture, to be delivered on the 16th inst., will deal with the question of the compulsory notification of tuberculosis.

THE LATE OPERATIONS ON THE INDIAN FRONTIER.

THERE was a large muster of members and guests at the Camera Club, Charing-cross-road, on Thursday, Nov. 3rd, when Major Beevor, R.A.M.C., Surgeon-Major of the Scots Guards, exhibited a series of views of the Indian frontier taken during the recent campaign. For some two hours Major Beevor kept his audience in rapt attention and brought the conditions of active service vividly before them.

Our Indian frontier lies upon a line drawn east and west along the very high range of mountains called the Samana range, at one end of which is a deep defile and at the other side a long line of hills called the Dargai heights where it will be remembered the Gordon Highlanders displayed such courage in storming the heights. The difficulties which our troops had to encounter and overcome could never have been brought home to people here except by the aid of photography and that art never received a better testimonial to its value than on Thursday when Major Beevor showed the results obtained by the camera in the field. The marksmanship of the Afridis was remarkable, though their boast that they could easily pick out a man's right eye from his left as a target was never demonstrated. The ridge above the heights was held by more than 8000 men, and so accurate was their fire that anyone who for a moment appeared in view was immediately shot. Indeed, had it not been that our men showed an utter disregard of certain death the sacred valley of the Afridis would never have been entered and the superstition that no white man even dared to look into it would have been verified. It must therefore be recorded to the honour of Colonel Mathias, of the Gordon Highlanders, that to his bravery we in a very great measure owe the initial victory. The accuracy of the reports of this gallant officer's speech on the heights of Dargai has been impugned, but Major Beevor vouches for the truth of the reported words. Standing upon a piece of high ground Colonel Mathias addressed his men and said—"The General says that position" (pointing to the top of the hills) "must be taken at all risks and the Gordons shall do it. Follow me." We need not dwell on the lecturer's description of the taking of the heights, as that story is now quite familiar to our readers, but there are other details which are interesting. Incidentally the lecturer mentioned that on one occasion while storming these heights the men in hospital broke out and all bandaged as they were rushed after their comrades to take part in the charge. As showing the deadliness of the enemy's fire on this occasion as many as 15 or 20 bullets were found in some of the killed. At the other side of the heights the men encamped in a valley and during the night were assailed by the enemy, who, however, received such a warm reception that they soon retired. On the following morning a man was found outside the camp with a quantity of string attached to his body and it is supposed that he had descended from the heights during the night to find a weak spot in the British encampment, the object of the string being apparently to signal to his companions where and when to make the rush.

The country of the Afridis is very mountainous and in some places almost impassable. The engineers, however, worked with so much will that the making of roads was only a question of time. On one occasion it took three hours to travel half a mile with the transport and on another ten hours to go four miles. Some parts of the country were found to be fertile and cultivated and the inhabitants, who were very industrious, understood agriculture and irrigation. In these places cherry, walnut, and apple trees grew in abundance. In some cases the hard rock was cut into terraces upon which were grown corn, barley, and rice. As was stated by the lecturer in his opening remarks the Afridis are very expert marksmen. Among the wounded were found wounds from almost every kind of sporting rifle and also from rifles of the best modern make. Of Dum-Dum bullets the enemy had a plentiful supply and in one of their raids they managed to capture 13,000 rounds. The number of wounds from this latter kind of bullet numbered many hundreds. The Afridis prefer the rifle, but have, however, an old-fashioned mounted gun called a jazail, which will fire anything, from stones, slugs, and pieces of telegraph wire to soldiers' buttons. Of this latter curious kind of ammunition it was no infrequent thing to receive a charge through the tents at night. Transport of the wounded was a very difficult matter owing to the ruggedness of the country and in crossing swollen mountain streams the occupants of the stretchers were sometimes precipitated into the water. The native mule-drivers in charge of the transport frequently deserted. The food was good but it was often impossible for the men to venture from under shelter to get it on account of Afridi sharpshooters.

Major Beevor concluded his remarks with a testimonial to the Sikhs, who, he said, were the finest men in the world and possessed excellent manners.

At the Camera Club on Nov. 28th Major Beevor will give an account of the use of the x rays in the field during the same campaign.

MUNICIPAL HONOURS AND THE MEDICAL PROFESSION.

WITHIN the last few years an increasing interest has been taken by the profession throughout the country in municipal affairs, and we venture to think that the corporations which have elected medical men as their mayors, while honouring the individuals, have done a good stroke for themselves in availing themselves of technical knowledge which is sure to be of the highest use. To emphasise this point let us review the usual committees in an average provincial corporation. There are the Watch, the Finance, the Works, the Sewage Outfalls, the Burial Board, the Waterworks, the Health, the School Attendance, the Lighting, the Technical Education, and in some towns we find a special committee for "the Housing of the Working Classes" as well as a Railway and Parks Committee. In at least six out of the first ten enumerated the services of the medical profession are eminently appropriate, while in one particular instance—that of the Health Committee—all will allow that there should always be at least one medical member on it. To be sure that this is so we have only to recall the work of a Health Committee the duties of which consist in carrying out the provisions of the Food and Drugs Act, the Public Health Acts, the Factory and Workshop Acts, the Contagious Diseases (Animals) Act, the control of a sanatorium or isolation hospital, of indoor and outdoor baths, of public abattoirs—in fact, the general sanitary supervision of the borough. When the control of sanitary matters is delegated to representatives of various trades and commercial enterprises, the presence of a medical man on a Health Committee must contribute to strengthen the position of the medical officer of health, while it will act as a wholesome stimulus in the matter of local sanitary inspection. The chief difficulty in the way of the active practitioner is the time required to perform the duties of a town councillor, but that an increasing number of gentlemen do not allow this to constitute a drawback to their participation in civic duties is seen by the list which we append of medical men who have during the past few days been elected to the office of mayor. The list is possibly not complete, as at the time of going to press full returns have not been received, but as it stands it constitutes a record:—

Carnarvon: Mr. Robert Parry, M.B. Lond., L.R.C.P. Lond., M.R.C.S. Eng., L.S.A. (re-elected). Chester: Mr. Henry Stolterfoth, M.A. Cantab., M.D. Edin. Conway: Mr. Morgan J. Morgan, L.R.C.P., L.R.C.S. Edin. Cowbridge: Mr. Richard Moynan, M.D., M.Ch. R.U.I. Coventry: Mr. T.

Webb Fowler, L.R.C.P. Lond., M.R.C.S. Eng., L.S.A. (re-elected). Darwen: Mr. J. T. Ballantyne, M.B., C.M. Glasg. Eccles: Mr. W. Moffett Hamilton, M.D., M.Ch. R.U.I., Dip. State Med. R.C.P.S.I. Harrogate: Mr. Ernest Solly, M.B. Lond., F.R.C.S. Eng., L.R.C.P. Lond., L.S.A., D.P.H. Eng. Hedon: Mr. James Soutter, L.R.C.P. Lond., M.R.C.S. Eng., L.S.A. (re-elected). Henley-on-Thames: Mr. James Lidderdale, M.R.C.S. Eng., L.S.A. (re-elected). Kingston-on-Thames: Mr. W. E. St. Lawrence Finny, M.B., M.Ch. R.U.I. Llandovery: Mr. R. Jeffreys Owen, L.R.C.P. Lond., M.R.C.S. Eng. Oswestry: Mr. William Alma Aylmer Lewis, L.R.C.P., F.R.C.S. Edin. (re-elected). Saltash: Mr. Robert T. Meadows, M.D., M.B., C.M. Edin., D.P.H. Eng. Conj. (re-elected). Ruthin: Mr. J. Medwyn Hughes, M.B., C.M. Edin. (re-elected). Totnes: Mr. G. J. Gibson, M.D., M.Ch. R.U.I. Winchelsea: Mr. Ernest W. Skinner, M.D., M.B., C.M. Edin. Worthing: Mr. Frank Parish, L.R.C.P. Edin., M.R.C.S. Eng.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In thirty-three of the largest English towns 6695 births and 3663 deaths were registered during the week ending Nov. 5th. The annual rate of mortality in these towns, which had declined in the eight preceding weeks from 24·6 to 17·9 per 1000, further fell last week to 17·0. In London the rate was 16·1 per 1000, while it averaged 17·6 in the thirty-two provincial towns. The lowest death-rates in these towns were 6·7 in Croydon, 10·4 in Derby, 12·2 in Huddersfield, and 13·0 in Bristol; the highest rates were 20·7 in Blackburn, 21·3 in Salford, 21·7 in Manchester, and 22·2 in Liverpool. The 3662 deaths in these towns included 420 which were referred to the principal zymotic diseases, against 538 and 455 in the two preceding weeks; of these, 123 resulted from diarrhœa, 91 from "fever" (principally enteric), 69 from diphtheria, 68 from measles, 43 from scarlet fever, and 26 from whooping-cough. No fatal case of any of these diseases occurred last week in Croydon; in the other towns the lowest zymotic death-rates were recorded in Brighton, Cardiff, Birmingham, and Bolton, and the highest rates in Portsmouth, Swansea, Wolverhampton, and Norwich. The greatest mortality from measles occurred in Portsmouth, Plymouth, Norwich, Nottingham, and Sunderland; from scarlet fever in Norwich; from whooping-cough in Halifax; from "fever" in Sheffield and Huddersfield; and from diarrhœa in Plymouth, Wolverhampton, Leicester, and Preston. The 69 deaths from diphtheria included 28 in London, 8 in West Ham, 7 in Swansea, 5 in Portsmouth, 5 in Liverpool, 4 in Leeds, and 4 in Sheffield. No fatal case of small-pox was registered last week in any of the thirty-three large towns, and no small-pox patients were under treatment during the week in any of the Metropolitan Asylums Hospitals. The number of scarlet fever patients in these hospitals and in the London Fever Hospital on Saturday last, Nov. 5th, was 3092, against 2728, 2915, and 3032 at the end of the three preceding weeks; 318 new cases were admitted during the week, against 357, 381, and 336 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 263 in each of the two preceding weeks, declined to 237 last week, and were 147 below the corrected average. The causes of 46, or 1·3 per cent., of the deaths in the thirty-three towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Nottingham, Salford, Leeds, Hull, and in fifteen other smaller towns; the largest proportions of uncertified deaths were registered in Birmingham, Liverpool, Burnley, and Bradford.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 19·0 and 20·0 per 1000 in the two preceding weeks, declined again to 18·9 during the week ending Nov. 5th, but exceeded by 1·9 per 1000 the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 17·4 in Dundee and 17·9 in Glasgow to 22·2 in Aberdeen and 28·9 in Perth. The 571 deaths in these towns included 32 which were referred to diarrhœa, 18 to "fever," 10 to diphtheria, 7 to measles, 7 to whooping-cough, and 6 to scarlet fever. In all, 80 deaths resulted from these principal zymotic diseases, against 86 and 73 in the two preceding weeks. These 80 deaths were equal to an annual rate of 2·7 per 1000, which was 0·7 above the mean rate last week from the same diseases in the thirty-three large English towns. The deaths referred to different forms of "fever," which had been 9 and 15 in the two preceding weeks, further rose to 18 last week, of which 11 occurred in Glasgow, 2 in Edinburgh, 2 in Paisley, and 2 in Greenock. The fatal cases of diphtheria, which had been 6 and 8 in the two preceding weeks, further increased to 10 last week, of which 5 were recorded in Glasgow. The 7 deaths from whooping-cough were within one of the number in the preceding week, and included 4 in Glasgow and 2 in Dundee. The fatal cases of scarlet fever, which had declined from 14 to 4 in the four preceding weeks, rose again to 6 last week, of which 3 occurred in Glasgow and 2 in Edinburgh. The deaths referred to diseases of the respiratory organs in these towns, which had been 120 and 119 in the two preceding weeks, rose to 126 last week, but were 16 below the number in the corresponding period of last year. The causes of 36, or more than 6 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had increased in the four preceding weeks from 22·1 to 26·4 per 1000, declined to 24·8 during the week ending Nov. 5th. During the past four weeks the rate of mortality in the city has averaged 25·5 per 1000, the rate during the same period being 17·1 in London and 18·9 in Edinburgh. The 166 deaths registered in Dublin during the week under notice showed a decline of 11 from the number in the preceding week, and included 18 which were referred to the principal zymotic diseases, against 20 and 13 in the two preceding weeks; of these, 6 resulted from diarrhœa, 3 from diphtheria, 3 from whooping-cough, 3 from "fever," 2 from scarlet fever, and one from measles. These 18 deaths were equal to an annual rate of 2·7 per 1000, the zymotic death-rate during the same period being 1·6 in London and 3·2 in Edinburgh. The deaths referred to "fever," which had been 4 in each of the two preceding weeks, were 3 last week. The 3 fatal cases of diphtheria corresponded with the number recorded in the preceding week. The deaths from whooping-cough, which had been 7 and 1 in the two preceding weeks, rose again to 3 last week. The mortality from scarlet fever and from measles also exceeded that recorded in the preceding week. The 166 deaths in Dublin last week included 42 of infants under one year of age, and 43 of persons aged upwards of sixty years; the deaths of infants showed a slight increase, while those of elderly persons showed a decline from the number in the preceding week. Six inquest cases and 5 deaths from violence were registered; and 52, or nearly a third, of the deaths occurred in public institutions. The causes of 16, or nearly 10 per cent., of the deaths in the city last week were not certified.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments are announced:—Surgeons: George E. Glynn to the *Galatea*; Francis F. Lobb to the *Alexandra*; Harold J. Chater to the *Colossus*; Herbert W. B. Shewell to the *Rodney*; George E. Macleod to the *Benbow*; Ernest S. Reid to the *Collingwood*; Harry E. Raper to the *Trafalgar*; Frederick C. B. Gittings to the *Nile*; and Alan G. Eastment to the *Howe*.

ROYAL ARMY MEDICAL CORPS.

Major W. R. Crooke-Lawless, the Royal Army Medical Corps, from Surgeon-Major, Scots Guards, to be Surgeon-Major, Coldstream Guards, vice Major W. C. Beevor, the Royal Army Medical Corps, who exchanges. Major W. C. Beevor, the Royal Army Medical Corps, from Surgeon-Major, Coldstream Guards, to be Surgeon-Major, Scots Guards, vice Major W. R. Crooke-Lawless, the Royal Army Medical Corps.

Digitized by Google

who exchanges. Lieutenant-Colonel J. Fraser, to be Colonel, vice W. D. Wilson, promoted.

Major Wilkinson embarks for India. Lieutenant-Colonel Keays, Major Yourdi, and Lieutenant Bowen are posted to the Punjab, Madras, and Bengal Commands. Captain Copeland is posted to the Western Heights, Dover. Major Phipps assumes Medical Charge at Warley, vice Major Morse, under orders for India. Major Thompson embarks for India.

ARMY MEDICAL RESERVE OF OFFICERS.

Surgeon-Lieutenant David James Lawson, 1st Dorsetshire Volunteer Artillery, to be Surgeon-Lieutenant.

VOLUNTEER CORPS.

Artillery: 3rd Durham (Western Division, Royal Artillery): James Henry Hunter to be Surgeon-Lieutenant. *Rifle:* 1st Roxburgh and Selkirk (the Border): Surgeon-Major J. S. Muir to be Surgeon-Lieutenant-Colonel. 3rd Volunteer Battalion the South Staffordshire Regiment: Surgeon-Lieutenant E. Morton resigns his commission.

VOLUNTEER OFFICERS' DECORATION.

The Queen has conferred the Volunteer Officers' Decoration upon the undermentioned officers of the Volunteer Force. *Eastern District: Rifle:* 1st Volunteer Battalion the Suffolk Regiment: Surgeon-Major Maurice Edward Ling. *Home District: Rifle:* 1st Bucks Volunteer Rifle Corps: Brigade-Surgeon-Lieutenant-Colonel William Henry Bull. *North-Western District: Rifle:* 3rd Volunteer Battalion the King's (Liverpool Regiment): Surgeon-Major Frederick Flood Moore, retired. 4th Volunteer Battalion the King's (Liverpool Regiment): Surgeon-Lieutenant-Colonel William Somerville Limrick. *Scottish District: Rifle:* 1st Roxburgh and Selkirk (the Border) Volunteer Rifle Corps: Brigade-Surgeon-Lieutenant-Colonel George Hogarth Turnbull.

LORD KITCHENER OF KHARTOUM.

IT goes without saying that the nation and the army alike are gratified that the Queen has been pleased to confer the dignity of a peerage upon Major-General Sir H. Kitchener, Sirdar of the Egyptian army, under the style and title of Baron Kitchener of Khartoum and of Aspall in the county of Suffolk. There is no need to dwell upon the great services, military and political, which he has rendered, for they are fresh in the recollection of all. It is somewhat rare, however, for a successful general to exhibit such qualities of statesmanlike tact and judgment under trying circumstances as Lord Kitchener has done. We may add that the medical services are among the foremost in their congratulations, for they are proud of the highly appreciative terms in which their work has been recognised on the occasion of the recent arduous campaign in the Soudan. We are glad to learn that the strain upon the military hospitals of Egypt has been much diminished, owing to the number of sick and wounded from Atbara and Omdurman having greatly decreased.

THE DIRECTOR-GENERAL OF THE INDIAN MEDICAL SERVICE AND SANITARY COMMISSIONER WITH THE GOVERNMENT OF INDIA.

We are glad to congratulate Surgeon-General Harvey, C.B., on his appointment to the above posts in succession to Surgeon-General Cleghorn, C.S.I., retired. Surgeon-General Harvey has had a long and varied experience in India in both the civil and military branches of his service and has gained much distinction and reputation in both directions. He joined the Indian Army March 31st, 1865. His war service includes the Bhootan expedition, 1865–66 (medal with clasp); the Looshai expedition, 1871–72 (mentioned in despatches, clasp); the Miranzai, first and second expeditions, 1892, as P.M.O. (mentioned in despatches, clasp and D.S.O.); the Hazara expedition, 1891, as P.M.O. (clasp); and the Izazai expedition, 1892, as P.M.O.

THE SUBORDINATE MEDICAL DEPARTMENT IN INDIA.

We are glad to notice that the Secretary of State for India has sanctioned the proposals of the Indian Government for improving the position of assistant surgeons of this very deserving and useful department. The subordinate medical service will in future be divided into four classes on Rs. 85, 110, 150, and 200 respectively, the existing class on Rs. 60 being abolished. Promotion will be given after certain fixed periods of service, the highest class being attained after nineteen years, instead of the present average of twenty-four years' service.

DEATHS IN THE SERVICES.

Brigade-Surgeon Frederick Pennington, at Lugano, in his sixty-ninth year. He entered the army in 1858 and retired in 1885. He was engaged in the operations against the rebels in Oude in 1858–59 (medal) and served in the Ashanti war of 1873–74 (medal). He also served in the Egyptian War of 1882 (medal and Khedive's Star).

"THE TITLES OF RETIRED ARMY MEDICAL OFFICERS."

In our paragraph under this heading in our last issue suggesting that the Royal Army Medical Corps titles should be conferred upon the retired members of the Army Medical Service our meaning is somewhat altered by an obvious printer's error. The word "but" at the end of the third line should, of course, be *non-*.

COLONEL SLOGGETT, R.A.M.C.

This officer is to be greatly congratulated on having made such a rapid and apparently complete recovery from the serious gunshot wound of the chest which he sustained at the battle of Omdurman.

ARMY MEDICAL SCHOOL, NETLEY.

On the departure for India of Professor Wright, Captain W. B. Leishman, R.A.M.C., will join the Army Medical School as Assistant Professor of Pathology.

Correspondence.

"Audi alteram partem."

THE EASTBOURNE PROVIDENT MEDICAL ASSOCIATION.

To the Editors of THE LANCET.

SIRS,—As you have taken an interest in the Eastbourne Provident Medical Association since its formation three years ago[1] you may be glad to hear something of its present position. The association does not print an annual report, but this letter includes all the important features of the report read at the annual meeting recently held. The association has completed the third year of its existence. Its membership now amounts to 5338. This is an increase of 1185 on last year's numbers. The population of Eastbourne is something under 44,000. We have had our acting medical staff still further strengthened this year by the addition to it of three old-established practitioners who hitherto have constituted the staff of the old Provident Dispensary. Between 700 and 800 members of that dispensary have followed their medical advisers and have become members of the Provident Medical Association. The income of the association for the past year has been £877 3*s.* 3*d.*, derived solely from members' payments and the payments for membership cards. On account of it having become necessary to employ a paid assistant-secretary the working expenses have been increased. The amount deducted for these expenses during the year has been 17½ per cent. of the income. The balance remaining goes directly to the medical staff. No complaints connected with the working of the association have been brought to the honorary secretary's notice during the year.

The most important event of the year is the addition to our acting medical staff of the whole of the medical staff of the old Eastbourne Provident Dispensary, which came about thus. In March last these three gentlemen received letters from the committee of the Provident Dispensary giving them notice that their appointments as medical officers to the dispensary would terminate at midsummer. The reason given them was that on account of the "considerable and continued diminution of the number of members of the dispensary in recent years" the committee considered "a revision of the remuneration of the medical officers was advisable." No opportunity was given to these gentlemen to continue as the dispensary medical officers even under "revised" salaries, although in their report issued only a month previously the committee had offered "their best thanks to the medical officers

[1] THE LANCET, Oct. 5th, 1895.

Digitized by Google

for their attention to the patients." On the contrary, the Dispensary Committee approached other medical men in the town with a view to their appointment to the dispensary in succession to the late staff. In the meantime the old staff of the Provident Dispensary applied for admission and were unanimously elected to the staff of the Provident Medical Association. During the month of June two medical men were found in Eastbourne who were willing to fill the vacancies caused by the dismissal of the staff of the Provident Dispensary. One of these two was at the time on the staff of the Provident Association, but he, of course, resigned on accepting the dispensary appointment. Our committee heard of this gentleman's action with the greatest regret and not a little surprise, for from the inception of the association our committee, while wishing to deal fairly with the Provident Dispensary, have always felt that it was conducted on lines which they could not approve. And yet these two gentlemen were willing to accept appointments under an institution worked on principles directly contrary to those which, after prolonged and careful consideration, the profession in Eastbourne had adopted as the only satisfactory lines upon which the medical treatment of the poor could be conducted (vide THE LANCET, July 27th, 1895).

The virtual dismissal of the Provident Dispensary staff forcibly illustrates the truth of the opinion of the association that it should not be possible for medical practitioners to be suddenly severed from their patients—even from those of the humbler classes—at the will of a committee composed mainly, if not entirely, of laymen. The remedy lies in the adoption of the principles of the Eastbourne Provident Medical Association, and the best evidence of the soundness of these principles is the steady growth in the number of our members. I may, in closing, mention that our methods have been adopted in New South Wales, where the Sydney and Suburban Provident Medical Association has been started, and has, I am informed, attained, in spite of considerable difficulties, "a creditable degree of efficiency."

I am, Sirs, yours faithfully,

ALEX. HARPER, M.D. Durh.,
Hon. Sec. Eastbourne Provident Medical Association.

Eastbourne, Nov. 8th, 1898.

THE ASSOCIATION OF PUBLIC VACCINATORS.

To the Editors of THE LANCET.

SIRS,—A general meeting of the Association of Public Vaccinators was held on Nov. 1st, in the offices of the Medical Defence Union, 4, Trafalgar-square, Mr. Greenwood, Public Vaccinator for Marylebone and President of the association, in the chair, for the consideration of the new vaccination order of the Local Government Board. The meeting, which was largely attended, included representatives from all parts of England and Wales.

The following recommendations have been communicated to all members of the association:—

1. That the fee to be applied for under Article 3, paragraph (*a*), of the order should be 2*s.* 6*d.* It was pointed out that this fee was in no real sense a fee on the birth-rate, since the number of births in which it is to be assessed is subject to such extensive deductions; and, again, that in every case in which the fee is payable at least one visit to the home of the child will be necessary.
2. That the fees provided for successful vaccination and revaccination at homes or elsewhere by Article (3), paragraphs (*b*) and (*c*) be accepted as a minimum.
3. That mileage be allowed for at the rate of one shilling per mile or part of a mile, one way, for distances greater than two miles from the public vaccinator's residence, for each statutory visit paid.

We trust that public vaccinators generally will take note of these suggestions in approaching their various boards of guardians. Any public vaccinators who have not yet joined the association may obtain particulars from either of us.

We are, Sirs, yours faithfully,

VICTOR A. JAYNES (157, Jamaica-road, S.E.),
ALBERT E. COPE (26, Bessborough-gardens, S.W.),
Nov. 9th, 1898. Honorary Secretaries.

"THE VACCINATION ORDER, 1898."

To the Editors of THE LANCET.

SIRS,—In your excellent article on the New Vaccination Order of the Local Government Board in your last issue there are one or two points you have not commented on, on which I should be grateful to you for an expression of your opinion.

In Schedule 1 (6) is the attendance on the child sick from vaccination to be paid for by the parents or is it to be given at the public vaccinator's expense? If in the first case the paragraph is unnecessary, if in the second it greatly increases the public vaccinator's responsibility, and should be considered in his remuneration. Again, it will frequently happen that both parents will be away when the public vaccinator calls, on the vaccination officer's order, and if he vaccinates, having only the consent of a child or other person in charge of the infant, would he be liable to be convicted for assault? And is the grant for successful vaccination now abolished?

I am, Sirs, yours faithfully,

Beckington, Bath, Nov. 6th, 1898. W. G. EVANS.

*** (*a*) The treatment by a public vaccinator of a child vaccinated by him and who, in his opinion, is suffering "in consequence of the vaccination," is to be carried out at the public vaccinator's expense. This requirement does not really increase the public vaccinator's responsibility. In all vaccination contracts hitherto the public vaccinator has always undertaken "to do all such acts and things to the best of his judgment" as "shall seem necessary for the purpose of causing such vaccination to be successfully terminated." This has always included advice, &c., for any ailment in consequence of vaccination; and the only difference is that whereas such advice and action is, under the existing system, probably limited to occasions when the suffering child is brought to the station, they must hereafter be given at the home of the child. Account of this in the case of these rare incidents was taken when the minimum fee of 1*s.* 6*d.* for stational vaccination was altered to 6*s.*; the latter being also a minimum. (*b*) If the public vaccinator has given notice to the parents as to the date of his intended visit, as required under the general order, it will devolve on the parents to make such arrangements as are necessary for the child to be vaccinated if they are away. The public vaccinator will have no further duty if the child is not available when he calls at the date specified.—ED. L.

THE STATE SERVICE IN ST. PAUL'S CATHEDRAL.

To the Editors of THE LANCET.

SIRS,—There is a growing conviction among medical men that the service in state yearly organised by the Guild of St. Luke in St. Paul's Cathedral possesses many highly objectionable features and tends decidedly to lower the profession in the eyes of the intelligent. To prove this latter contention the general tone of the notices of the function in the lay journals is sufficient, and if the members of the Guild were not so very thick-skinned these notices would themselves be sufficient to deter them from repeating their annual display.

Unlike some other professions, that of medicine has never been given to show. A public muster of members in gorgeous attire is in itself an innovation requiring some justification, but the matter becomes much more serious when we remember that this display is preceded by preliminary puffs in nearly all the lay papers, evidently inspired, wherein certain names are given, and that notices of the function are inserted in most lay and religious papers, names being again introduced. What is this but advertisement? Yes—advertisement of a most insidious and reprehensible character, for not only do those whose names appear advertise their persons and occupations, but they also contrive to establish in the minds of the weaker sort a reputation for piety. The Guild cannot in reason plead religious enthusiasm in mitigation of their offence; for the Founder of Christianity, whose followers they profess to be, has sternly forbidden any such display. In His Sermon on the Mount, Mat. vi., 5 and 6, occur these words: "And when thou prayest, thou shalt not be as the hypocrites are: for they love to pray standing in the synagogues and in the corners of the streets, that they may be seen of men. Verily I say unto you, they have their

Digitized by Google

reward. But thou, when thou prayest, enter into thy closet, and when thou hast shut thy door, pray to thy Father which is in secret; and thy Father which seeth in secret shall reward thee openly."

I am, Sirs, yours faithfully,

Bowes Park, N., Nov. 7th, 1898. ANGUS CAMPBELL.

"THE WATER TEST AS APPLIED TO SEWER CONNEXIONS."

To the Editors of THE LANCET.

SIRS,—I have read with interest the letter in THE LANCET of Oct. 29th by Mr. J. W. Mayne on the above subject. I quite agree with him that the connecting drain to the sewer is often carried out in an unsatisfactory and slipshod manner, but I do not quite understand Mr. Mayne's difficulty. Why should he not test the connexion put in by the local authorities himself? It can easily be done and without very much trouble, and if found leaky and defective, as he seems to think it would be, surely he can compel the persons who have done the work and charged him for it to make it good. I make a point of testing all sewer connexions three or four days after they are executed, and this has been done in a connexion made last year from a large hospital in Mr. Mayne's own district (Wimbledon).

In London, where there are often large brick sewers, the thing is simple enough—to plug the drain from the sewer in the ordinary way, seeing that the plug is secure and water-tight, and then test. I may say that I have always found the authorities willing and ready to help me in this matter. Only this week on a very large drainage work I am carrying out at the Incorporated Law Society in Chancery-lane I have had three separate connexions made with the sewer (which are under the jurisdiction of two distinct authorities) and tested in the above manner, although it was necessary to walk a great distance up the sewer in order to get at the connexions to see that they were effectually plugged, and these plugs were in the drain while it was filled with water for 24 hours and three days after the work was executed.

For small pipe sewers of course this method is not possible, so I have the connexions tested by means of one of the inflated bag plugs. The distance to the sewer can easily be ascertained and the bag pushed down the connecting drain nearly to the inlet to the sewer and then inflated by means of the rubber tubing (the bag should be held also by means of a cord), the drain then tested by water, and afterwards the bag emptied and withdrawn. I have no doubt whatever that, as Mr. Mayne states, many miles of defective connexion to sewers are laid and are a source of great danger, but this might, I think, be largely overcome if proper professional supervisors were employed who would insist on seeing that the work was carried out in an effectual manner.—I remain, Sirs, yours faithfully,

H. PERCY ADAMS, F.R.I.B.A.

Woburn-place, W.C., Nov. 4th, 1898.

To the Editors of THE LANCET.

SIRS,—Mr. Mayne's letter in THE LANCET of Oct. 29th impels me to give a recent experience. A relative of mine was taking a house in a London suburb. By my advice the agreement was not signed until the drains had been tested. They were exposed in the garden as far as the street; the smoke test was applied; smoke issued from every joint without exception. As usual the joints had been cemented in front but not behind (out of sight). This is an old story, but it needs repetition. My friends would have "backed their luck" unless I had been urgent with them, although, strange to say, their drinking-water is taken from a well in the garden and the drain-pipe passes within 8 ft. of it.

I am, Sirs, yours faithfully,

Nov. 7th, 1898. T. C.

INVERSION OF UTERUS CAUSED BY A "MIDWIFE."

To the Editors of THE LANCET.

SIRS,—In THE LANCET of Oct. 22nd I notice an annotation headed "Midwives and the Deaths of Children." I think that the following facts will confirm the opinion expressed that the mothers' and the children's lives are sacrificed by the absence of proper medical attendance.

Not many weeks ago I was called to see a midwifery case; the message was that "the midwife could not manage." On arrival at 4 A.M. I found that the patient had been delivered of a female child at 3 A.M. by an "uncertificated midwife." The patient was dead, lying on the bed in the obstetric position, and on examining the body I found the following state of things. The uterus was entirely inverted, the whole of the uterus lying on the sheet under the patient, only the broad ligaments remaining in the vagina. The placenta was attached to the fundus of the uterus and had been adherent, but two-thirds of the placenta were separated from the placental site, no doubt due to force employed by the midwife; the remaining third I peeled off and returned the inverted uterus into position. There had been considerable hæmorrhage. On questioning the "midwife" she told me that she was called to the deceased at 7 o'clock on the previous evening and that the labour pains were irregular and often at fifteen minutes' interval, that the child came naturally, but when "she went to get the placenta," repeating her own words, the deceased bore down and that it all came at once. The deceased was an anæmic woman in poor circumstances, and this was her second child. The so-called "midwife" stated at the inquest the same as she told me, that she had attended cases for seventeen years and never had a fatal case or one with any serious complications before, and that she had had no training except what she had learnt from her own experience. The coroner severely censured the "midwife" and told her that she would in attending cases do so at her own risk. There can be no doubt, as I stated at the inquest, that the "midwife" made traction on the cord and that the placenta being adherent to the fundus caused the inversion; but the inversion was caused by the ignorance on the part of the midwife and thus brought about a fatal result.

When one reads of cases in THE LANCET of certificated midwives giving ergot before the delivery of the child and then has such a case as this one it impresses the fact more clearly that the sooner these so-called "midwives" are registered and act under proper medical advice one will not see such a lamentable result as the foregoing.

I am, Sirs, yours faithfully,

RICHARD G. WORGER, M.R.C.S. Eng.

Radstock, Somerset, Nov. 1st, 1898.

THE DIPLOMA IN SANITARY SCIENCE OF THE ROYAL UNIVERSITY OF IRELAND.

To the Editors of THE LANCET.

SIRS,—I have once before in the medical press called the attention of the Senators of the Royal University of Ireland to the absurdity of continuing to offer to its medical graduates a qualification which is called "Diploma in Sanitary Science" to candidates passing a qualifying examination in a number of subjects similar to those specified for the D.P.H. Cambridge, or D.P.H. London conjoint colleges examinations. The title of the diploma too nearly resembles that of a qualification such as is usually given to a sanitary inspector. Is a man going to spend six or twelve months in close study and laboratory work to be rewarded with a mere Diploma in Sanitary Science? Evidently the medical graduates of the Royal University of Ireland think such a prize is not worth seeking, for on looking through the University Calendars I find such a diploma offered annually for the last seven years or so, but no record is to be found of anyone having obtained this qualification. Its graduates have to go to other licensing bodies and universities for their Diplomas in Public Health. There is no difficulty in seeing that the fault lies in the name of the diploma this University offers. Therefore I address myself to the Senators of this University through the medium of THE LANCET to remedy the title of the diploma they offer in the special branch of Public Health. And I would venture to suggest (1) either that the name of the diploma be changed to D.P.H. R.U.I., or (2) preferably, as in the University of Edinburgh, that they give after proper examination a B.Sc. (Hygiene). I feel sure if either change be made there will be many graduates going up for the special Diploma in Public Health instead of as at present.—I am, Sirs, yours faithfully,

CHARLES LEO BIRMINGHAM, M.D. R.U.I.

Highgreen, Yorkshire, Nov. 4th, 1898.

THE OXFORD MEDICAL MISSION.

To the Editors of THE LANCET.

SIRS,—Your annotation in THE LANCET of Nov. 5th, entitled "The Abuse of Medical Charities," conveys an

Digitized by Google

erroneous impression of the Oxford Medical Mission. This is one of the branches of the Church in Bermondsey and its object is the special care of the sick and dying among the poorest classes. Complaint was made at the inquest referred to that patients were treated at the Mission without regard to their circumstances. This is not true. Inquiry is always made and patients are daily refused. I have made special inquiry about the child referred to. I learn that the mother was wholly without means and was supported by friends while looking for work. The child was only seen once at the mission house. It was brought again when none of the medical staff were present and the mother appears to have been referred by the clergyman to the nearest practitioner. I may say that in any case you cannot call this an "abuse" of a medical charity, seeing that the funds are almost wholly provided by the secretary and a few Oxford men who know perfectly well how their money is used. When the Mission was started last winter I called on a number of the local medical men and said we were most anxious not to interfere with their practice and that if ever they pointed out to us a case of undeserved treatment we would stop it at once. We have had no complaint and one leading medical man has given us most valuable help.

I am, Sirs, yours truly,

JOHN STANSFELD, M.A. Oxon., M.R.C.S. Eng.,
Nov. 9th, 1898. L.R.C.P. Lond.

"THE LANCET ANALYTICAL COMMISSION ON SHERRY: ITS PRODUCTION, COMPOSITION, AND CHARACTER."

To the Editors of THE LANCET.

SIRS,—We read in THE LANCET of Nov. 5th a letter from Dr. H. Howard Murphy respecting your very able article on the above-named subject. Dr. Murphy says that having questioned several friends "in the trade" he is assured that the blending of sherry is essential and universal, and that the blending consists of adding water, spirits, curaçoa, burnt sugar, &c. How any members of our trade can have made such a statement as this surpasses our understanding, for, speaking with many years' experience, we are in a position to say that Dr. Murphy has been grossly misled.

We are sherry shippers and have the pleasure of shipping Jerez wine—sherry such as described by your Commissioner—to many of the leading wine merchants in the United Kingdom, firms old-established and of the highest integrity, and we shall be pleased to put Dr. Murphy in communication with any of them he may wish, when we are certain they will to his satisfaction prove the sherry that they import is supplied to the public exactly as they receive it and that in the vast majority of cases it is bottled straight from the cask in which it is imported. Different vintages of sherry are blended together in Spain but not in England; blending of this kind, however, is a very different thing to the mixing of wine with the ingredients named by Dr. Murphy's informants.

We trust that Dr. Murphy will investigate the matter further, when we are convinced that he will be satisfied that he can with every confidence recommend the wine, upon which we are, indeed, glad to see you have been able to report so favourably.

We are, Sirs, yours faithfully,

WILLIAMS AND HUMBERT.
17, Mincing-lane, E.C., Nov. 7th, 1898.

P.S.—We take this opportunity of pointing out, also, that in a paragraph in the *St. James's Gazette* of Nov. 3rd it is stated that fine sherries are not to be obtained at a price which brings them within the reach of all and that fiery blends coming *viâ* Hamburg take the place of choice dinner sherry. This is not so. Genuine and good sherry is now cheap and the most humble cellar could contain a small stock, and, moreover, Cadiz wine is now lower in price than any blend coming from Hamburg; so that there could be no object in importing from that port. We have the best authority for saying that the amount of white wine now coming from Hamburg to the United Kingdom is infinitesimal.

THE MOSQUITO AND DRINKING WATER.

To the Editors of THE LANCET.

SIRS,—Is it advisable to allow the mosquito to have access to drinking water? In view of recent research work I should certainly think not. And when the water-supply is in the vicinity of dwellings the recent work connecting the mosquito with malaria appears to discountenance such a proceeding. But apparently this view of the matter is not accepted by all tropical practitioners, for I know at least one gentleman who advocates that mosquitoes should be encouraged to breed in water-supply, on the ground that by devouring any organic matter which may be present the larvæ purify the water. I am, Sirs, yours faithfully,

Nov. 5th, 1898. C. H. E.

THE GENERAL MEDICAL COUNCIL AND THE UNQUALIFIED ASSISTANTS.

To the Editors of THE LANCET.

SIRS,—Am I mistaken or is it really the case that in spite of its regulations the General Medical Council will not take the initiative in enforcing their observance? I am informed that any grievance which one practitioner may have against another in the matter of unqualified assistants will receive no attention if reported to the Council. Or, to be plainer, the Council will simply act as a tribunal before which a case of the kind may be brought, but the conduct of the case and the expenses thereof are left to the complainant. The Pharmaceutical Society protects those whom it registers and on information investigates and prosecutes offenders. Surely registered medical men merit the same protection from the General Medical Council. It is a very unpleasant thing for a man to have to act as his own policeman. Often among a number of medical men in a small town only one of them will be at all injured by another keeping an unqualified assistant. For two reasons he has to quietly submit to this unfair opposition. First, informing the General Medical Council privately is of no use; he must occupy the invidious position of prosecutor. Secondly, were he willing to do this the expense is prohibitive. The result of this is that the Council's late regulation is set at defiance by all who think they can do so safely.

In my own case one of my opponents employs and sends round visiting patients in my district an unqualified man. I am obliged to put up with it or render myself odious to those among whom my opponent and his assistant are popular by acting as his prosecutor. Were the General Medical Council ready to take the initiative on my positive information my path would be perfectly smooth, as, though I am the only man affected by this breach of the regulations, there are others who for aught the public know might be the informants. I also know of another case in which a personal friend of my own is acting as unqualified assistant to a practitioner who has a lucrative practice as well as private means. His salary is £30 a year and time for attending classes. Only last month appeared an advertisement for a surgery attendant "able to ride and cycle." What does that mean? Simply an unqualified assistant and the setting at defiance of the Council's regulations. The unqualified assistant would disappear entirely and a great injustice to medical men in a small way of practice be removed if the Council would do its rightful duty and enforce the observance of its laws with its own hand.

I am, Sirs, yours faithfully,

Nov. 7th, 1898. JUSTICE.

NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT.)

The Plague Commission.—Rabies in India.—Madras and its Plague Measures.—The Progress of the Plague.—The New Plague Regulations.—The English Plague Nurses.

THERE is plenty of work for the Plague Commission—the only regret is that it was not appointed sooner. The immense quantity of plague literature which has been accumulated consists for the most part of official reports and from a medical point of view is of little value. It is said that the Commission will deal chiefly with the origins of the different outbreaks, the manner in which the disease is communicated, and the effects of curative serum and preventive inoculation. It is to be hoped that it will collect evidence from unofficial and independent persons. The two civil officers of Indian experience are Mr. J. P. Hewett, secretary to the Government of India Home Department, and Mr. A. Cumine, I.C.S. The names of the medical members have not yet been published here. Mr. C. T. Halifax, Deputy Commissioner, Lahore, has been selected for appointment as secretary.

Almost every week some European is bitten by a rabid dog

Digitized by Google

and travels to Paris for treatment at the Pasteur Institute. Now five soldiers have just been sent. Rabies is rife in nearly all parts of India and these accidents are constantly occurring, yet the establishment of an institute for India is treated with indifference and the anti-vivisectionists are active and take every opportunity to vilify the work of Pasteur and his successors.

Different Presidencies adopt different plague measures. For Madras the Government have declared its willingness to contribute towards the cost of erecting private plague hospitals while leaving the internal management to certain native practitioners who enjoy the confidence of the people. The Government will pay half the cost of construction and half the cost of maintenance, provided the arrangements meet with the approval of the local medical officers, the collector, or the president of the municipality. How different all this is from the regulations made in the Bombay Presidency. Although Madras city has had for some time an excessively high death-rate the authorities indignantly deny that it is due to unrecognised or concealed cases of plague, but it is admitted that the sanitary state of the city is very bad. In some districts there are few or no drains, crowding is excessive, and an enormous waste of water keeps the subsoil perpetually damp. It is said that cholera has been more prevalent than has been reported and that there has been an increase of population by immigration from certain distressed districts. The system of registration of the causes of death seems to be as bad as in Bombay. It is dependent upon ignorant persons who cannot be expected to furnish correct returns. Anything that is not fever or cholera or dysentery will generally come under the head of "other diseases." Beyond the daily or weekly totals of deaths such returns are absolutely valueless.

The progress of the plague during the past fortnight has been irregular. While there has been an extraordinary interruption in its development in Bombay city it continues severely in the Dharwar, Belgaum, and Satara districts and in Bangalore city it is gaining ground rapidly. If the diminution of plague deaths in Bombay is due to the excessive heat of the past fortnight there is no hope for improvement with the onset of cooler weather. It cannot be due to the measures taken against the plague because now it is practically left to take its own untrammelled course. The Presidency plague returns for the past week show an increase in the number of attacks, but a slight decrease in the total of fatal cases. The numbers were 5803 attacks and 4311 deaths, as compared with 5637 attacks and 4394 deaths in the previous week:—

—	Cases.	Deaths.
Cities.		
Bombay	290	211
Karachi	61 (?)	61 (?)
Poona	2	0
Districts.		
Kaira	8	8
Broach	19	14
Surat	13	14
Thana	44	41
Nasik	198	105
Poona	106	63
Satara	670	486
Sholapur	36	21
Belgaum	1696	1150
Dharwar	1574	1273
Political agencies.		
Baroda	172	99
Kathiawar	109	86

Cutch	46	36
Rewa Kantha	11	6
Pelanpur	—	1
Akalkot	12	10
Aundh	29	20
Bhor	71	52

The total from September, 1896, to October 14th, 1898, is 158,379 cases and 125,239 deaths.

The new plague regulations which were announced several weeks ago have at last been published. They concern chiefly the travelling public. The Government has now come to the conclusion that "as a permanent feature of epidemic regulations detention camps and passes are impossible. It is evident that it is impracticable over a large area and a prolonged period of time to close the ordinary channels of daily business and intercourse without very sorely trying the patience of the public and jeopardising general prosperity." This was pointed out in the press twelve months ago. Detention camps and passes will consequently be abolished. To replace detention camps and passes a very strict medical examination, accompanied by disinfection of clothing where necessary, will be instituted at convenient railway centres and at places of arrival. Persons coming from infected localities will also be subject to surveillance for ten days after arrival. Elaborately detailed instructions are publicly issued with regard to the examination of travellers. At each examining station the examination should be conducted in the same way as for passengers departing by sea from Bombay. For first- and second-class passengers and purdah ladies (!) the usual pulse examination will suffice. Does the Government imagine that such an examination is anything more than a farce? Plague cannot be detected by such means. Third-class passengers, except purdah ladies (!), must be required to detrain. There must be stationed women qualified to make the examination of travellers of the female sex. Whom do the Government recognise as qualified? There are certainly not lady doctors at all the examining stations and, as a matter of fact, a large part of the examinations are left to more or less trained nurses. There are, in addition, detailed rules with regard to the use of the thermometer, as if the Government had not confidence in its own medical officers. Persons travelling with certificates of inoculation will *ordinarily* be allowed to pass the examination prescribed for first- and second-class passengers except that they will probably be required to detrain and disinfection of clothing, bedding, and baggage, may be enforced. It is difficult to see what benefit inoculated persons derive from this rule. The same half-hearted support to inoculation is given in Bengal, where it is officially notified that the Government has ruled that persons inoculated by M. Haffkine's process, unless actually suffering from plague, shall be exempted from detention at plague observation camps in Bengal except for such period as may be required to disinfect baggage and clothes if they are considered suspicious. As detention camps will probably be abolished everywhere, as has just been notified for the Bombay Presidency, this concession to inoculated persons is of little value. It is evident that travelling is to be made as inconvenient and troublesome as possible. After having gone through the process of minute examination and perhaps disinfection of clothes the traveller will be given a ticket showing his identity. This will be operative for twenty-four hours. Even when he arrives at his destination he will still be subject to surveillance for ten days. When it is borne in mind that on an average one case of plague has been discovered amongst about 30,000 travellers some idea of the value of these elaborate regulations can be gathered. There is at any rate one new regulation of great importance. "No subordinate will be empowered to order detention or to decide as to the results of examination." The amount of blackmail which has been hitherto levied by subordinates has been at the root of a great deal of the ill-feeling created by the old regulations. As these new regulations were delayed in publication in order that the provisions might be discussed with the heads of the Government of India at Simla it may be assumed that what has been decided for the Bombay Presidency will ultimately be carried out in India wherever plague occurs in epidemic form. Up to the present time there has been no uniformity in the measures carried out and the measures have varied from extreme severity to practical uselessness. The Government have been compelled to modify and relax the regulations. It was imagined at first that elaborate and stern measures would eradicate the plague. It is only too clear that they have not. The plague will practically be allowed to take its own course, and it is hardly a prophecy to say that the new regulations with regard to travellers will have to be modified and relaxed at no very distant date. The movements of hundreds of thousands of people cannot be interfered with for an indefinite time.

Most of the English nurses who were sent out by the

Digitized by Google

Secretary of State for India have been asked by the Government of India to continue service for another year. Many have declined and have returned to England as soon as the term of their agreement was fulfilled. Several, however, have accepted the fresh agreement, which is somewhat different from the old. There is no increase of pay offered and there is no provision made for leave. Although it was found necessary to allow the nurses first-class travelling expenses in the Bombay Presidency this is not guaranteed, nor is the second-class return to England by the Peninsular and Oriental Steamship Company, as the Government reserve the option to themselves of paying the sum of 450 rupees instead. Service for one year is enforced on the nurse, but the Government can dispense with her services after six months. It is difficult to see what attraction these ladies see in these appointments to induce them to prolong their engagements. The work itself is unpleasant and sometimes arduous, and the pay is not so large as to make up for all other disadvantages. The novelty of Indian life and scenery when not changed soon passes off and from a professional point of view a year or two years at this kind of work must distinctly deteriorate the capacities of any woman as a modern well-trained nurse.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

The Prevention of the Spread of Consumption.

AT a recent meeting of the Health Committee of the City Council it was resolved to have printed for circulation handbills giving advice for the prevention of the spread of consumption. This, it is pointed out, is a disease which is said to be not inherited but contracted, and is therefore properly a preventable disease, though one of the most fatal, causing 1 death in every 10 in England. It is shown that it is almost always taken from a person who is suffering from the disease or through infected air, milk, and possibly meat. Intemperance, overcrowding, bad air, darkness, dampness, cold, sore-throats, &c., make people more liable to take consumption. The handbill gives directions in plain language for preventing the spread of the disease, and the coöperation of various associations and societies is asked to assist in making known the importance of the details noted.

Prevention of Cruelty to Children.

The tenth annual meeting of this society was held on Oct. 28th. The complaints for the year were 806, as compared with 725 last year—namely, general ill-treatment, 88; abandonment and exposure, 10; immorality, 7; neglect, 669; begging, 22; other wrongs, 9; and assault, 1. Of these there were convicted, 40; discharged, 3; warned, 620; otherwise dealt with, 111. Of these cases proceeded against there were, legitimate, 2135; illegitimate, 96; nurse children, 8; stepchildren, 27; other children, 27. The financial statement showed a remittance of £65 15*s.* 3*d.* from the branch to the central society, the number of subscribers on the books being 1214.

Hospital Sunday.

The amount collected at the various churches and places of worship on Hospital Sunday, Oct. 30th, is recorded at £5075 6*s.*, the proceeds this year going to the General Hospital.

Nov. 9th.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

University College, Liverpool: Medical School Building Fund.

THE fund which is being raised for new buildings for the departments of anatomy, medicine, and surgery has now reached the substantial sum of £13,000, thanks to the additional contributions of £5000 from Mrs. George Holt and Miss Emma Holt and £1000 from Mr. John Rankin. As only £4000 or £5000 more will be required to complete the necessary amount, the governors have asked that plans for the construction of the building may be submitted to them in order that the work may be proceeded with as soon as possible.

Honour for Professor Oliver Lodge.

The Rumford Medal of the Royal Society has been bestowed upon Dr. Oliver Lodge, F.R.S., the Professor of Physics in University College.

The New Professor of Midwifery and Gynæcology in University College, Liverpool.

Dr. Henry Briggs, the newly-appointed Professor of Midwifery and Gynæcology in University College, has had a very creditable record for hard work since his first appointment in 1877 as Demonstrator of Anatomy in the old Royal Infirmary School of Medicine, for which he was recommended by Sir William Turner of Edinburgh. After filling several minor but important posts he became connected with the Lying-in Hospital and the Hospital for Women, Shaw-street. He has devoted himself exclusively for many years to the practice of midwifery and gynæcology, and he has published some valuable contributions to the literature of those subjects. He is ex-President of the North of England Obstetrical and Gynæcological Society.

Hospital Sunday and Saturday Funds.

A meeting of the committee of these funds was held on Nov. 7th at the town-hall under the presidency of the Lord Mayor. The annual report and statement of accounts were adopted. The total receipts, including £405 brought forward from last year, amounted to £13,003 8*s.* 11*d.*, and the grants to the different charities amounted to £12,000. After payment of printing and advertising expenses there remained a balance of £490. The Saturday Fund exceeded the Sunday Fund by £102.

Medical Visitor to Licensed Houses under the Lunacy Act.

Dr. James Barr, physician to the Royal Infirmary, has been reappointed an additional visitor to houses licensed under the Lunacy Act within the city of Liverpool.

The Liverpool Select Vestry and Vaccination.

The Select Vestry at their recent meeting passed the following resolution unanimously: "That the Local Government Board be informed that the Select Vestry feel strongly the undesirability of wholly discontinuing in the parish of Liverpool the use of the public stations for the purpose of vaccination; and that the Board be requested to sanction the use of them by way of trial for a period of twelve months." The resolution arose out of the order of the Local Government Board to close the public stations on Dec. 31st, after which date the public vaccinators will be required to vaccinate infants at their own homes.

The Royal Infirmary and the Workmen's Compensation Act: Action at Law.

The committee of the Royal Infirmary have had to defend an action in the Liverpool County Court in which a laundry hand at the infirmary sought to recover from the trustees £300 for the loss of a finger and other injuries to the left hand which had been drawn into a steam wringer whilst she was in the respondents' employ. The plaintiff contended that a returned nurse's apron was sent to her and though she was on that day engaged in the ironing room it was not contrary to her duty to proceed to the washing room and use the wringer for the purpose she was doing. She admitted that it would not be her duty to wash or deal with the servants' aprons, which in due course would be washed at a different laundry and by different laundry maids. For the defence it was alleged that the apron which the plaintiff was attempting to pass through the wringer was an apron belonging to a servant at the infirmary who was then away on her holiday; that she had no right to go into the washing room, but she took the opportunity of it being the tea hour to hurriedly pass this apron through the wringer for her own purpose during the absence of the head laundry maid; and that in her haste she carelessly allowed her finger to become entangled in the machine. After the accident, upon an examination of the machine, the apron was found in it dry, and it was not a nurse's apron, as alleged by the plaintiff, but a servant's. The judge found for the defendants on the ground that the apron belonged to a servant, and that by passing it through the machine the plaintiff was not doing work for her employers but for own purposes and use. The defendants did not ask for costs.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Glasgow University.

THE graduation ceremony on Nov. 3rd attracted a crowded audience, the undergraduate element being exceptionally strong. In view of recent events the occasion was anticipated with some anxiety both by the University authorities and the Students' Representative Council. The good sense of the majority, however, asserted itself, and though the ceremony was hardly conducted in a strictly orderly atmosphere the proceedings passed off successfully and with good temper. As is usual at this period of the year the medical graduates were not numerous. Six gentlemen received the degree of M.D., Mr. J. T. Biernacki, M.B., Mr. H. H. Thomson, M.B., and Mr. Alfred Webster, M.B., being respectively awarded "commendation" for graduation theses. Under the old regulations 13 candidates graduated M.B. and C.M.; whilst 18, according to the new style, received the degrees of M.B. and Ch.B., Mr. James Barrowman graduating "with commendation." Amongst the new medical graduates it is noteworthy that there are no less than 7 of the lady students from Queen Margaret College. The same college, too, supplied some very distinguished graduates to the other faculties. Thus, for the M.A. degree Miss Elizabeth Pettigrew Taylor graduated with first-class honours in mathematics and second-class honours in English, Miss Helen Rutherfurd with first-class honours in classics, Miss Helen Rule with first-class honours in English, and Miss Daisy A. M. Clark received the degree of B.Sc. in pure science. Quite a feature of the graduation was the hearty reception which the lady graduates received from the students.

Glasgow Philosophical Society.

The current session was opened on Nov. 2nd, when an address was delivered by the President, Dr. Ebenezer Duncan, on Recent Social Progress in Scotland. The address was a continuation of a former paper in which Dr. Duncan traced the ancestry of the Scottish people and maintained that they were more Teutonic than the English. To this strain he attributed certain of their virtues and on the present occasion he discussed the vices known to be specially associated with the Teutonic races—viz., drunkenness and sexual immorality. By an elaborate series of statistics arranged from many points of view he showed that together with a decrease in the consumption of alcohol per head of the population there had been a decrease in the number of deaths from delirium tremens and liver disease in Scotland, whilst an increase in the use of ardent spirits in England had been attended by an increase in the number of deaths from these causes. On the subject of sexual immorality Dr. Duncan, by taking the number of illegitimate births in various districts, argued that this was more common in those of Teutonic than in those of Celtic descent. Amongst both, however, there was decided evidence of improvement in recent years. Related to both the above considerations is the fact that pauperism in Scotland has much diminished during recent years, whilst insanity, if it has not actually diminished, has certainly not increased. In conclusion Dr. Duncan expressed the opinion that the growth of great city communities was likely to lead, not to a deterioration of the race, but to a higher standard of physical life and a nobler development of moral character. At the same meeting Dr. W. J. Fleming demonstrated a simple and inexpensive method of localising objects by means of the x rays.

University of St. Andrews.

Mr. James Stuart, M.P., has been unanimously elected Lord Rector of the University.

University of Aberdeen.

The opening address for this session at the Aberdeen University Medical Society was delivered by Professor Hamilton, whose subject was Self-help in the Study of Medicine. Professor Cash occupied the chair.—The University Assistants' Association has been reconstituted on a broader basis under the title of the Aberdeen University Association of Lecturers and Assistants, with Dr. John Gordon as President and Herr G. Hein and Dr. David Rennet, assistant professor, as vice-presidents; Dr. Murray is treasurer and Dr. Warrack and Dr. Findlay are members of committee.—The annual report of the Students' Representative Council shows that during the past year the total membership was 34, made up as follows: arts, 12; medicine, 15; law, 3; divinity, 2; and science, 2. During the year 12 meetings were held, and there is a balance in hand of nearly £36. Only two new students have entered the University Divinity Hall this session, and at the opening meeting of the Church of Scotland Students' Association Professor Cowan, one of the honorary vice-presidents, delivered an address on the Causes of the Diminution of Divinity Students throughout the Church. In the course of his address he said that not many years ago the number of licentiates was believed to exceed the Church's requirements, while at present attention had emphatically to be called to the fact that the supply was now too small for the need.—The bust of the late Mr. Charles Mitchell, LL.D., Jesmond Towers, Newcastle, a liberal friend to the University, was unveiled in the Mitchell Hall early this week. The bust has been presented to the university by Dr. Mitchell's son, Mr. C. W. Mitchell.

Aboyne (Aberdeenshire) Isolation Hospital.

It has been remitted to the chairman of the Deeside District Council and Dr. Watt, county medical officer, to report as to the propriety of enlarging this hospital, where cases of enteric fever had lately to be refused owing to the whole accommodation being taken up by scarlet fever patients of both sexes.

Morningside Hospital, Aberdeen.

At the close of the hospital year there were 69 adult patients (labouring under incurable disease). Steps are to be taken for the erection and maintenance of a children's wing, and a donation of £1200 from the Thurburn trustees has been set aside as the nucleus of a building fund. Meantime, two small wards in the main building, each capable of accommodating five cots, have been prepared for the reception of children. The whole expense of the institution is £25 19*s.* 5*d.* per inmate per annum, but there was a net deficiency on last year's accounts of £37 17*s.* 6*d.*, and an appeal to the public for further aid is made.

Nov. 9th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Royal Academy of Medicine in Ireland.

THE opening meeting of the session took place on the evening of Nov. 4th, when the Pathological Section, under the presidency of Professor Purser, met at the hall of the Royal College of Surgeons in Ireland.

The Royal College of Surgeons in Ireland.

The Professorship of Midwifery and Gynæcology, rendered vacant by the resignation of Dr. Samuel Mason, is about to be filled by the Council of the College. Dr. H. C. Tweedy, Dr. More Madden, Mr. Andrew Horne, and Dr. Frederick Kidd are candidates for the office.

Belfast Maternity Hospital.

A public meeting was held on Nov. 2nd in the Town Hall (the Lord Mayor in the chair) in aid of the rebuilding of this old Belfast charity, which was started more than 100 years ago. It is entirely managed by ladies, and they propose first to build a new wing at a cost of £2000 and afterwards another building at a cost of £4000. There can be no doubt that the extension of the hospital is much needed both in the interests of poor women (as there is not by any means sufficient accommodation at present), and also as a most important factor of the medical school in Belfast, as it is in this institution in the main that the medical students receive their clinical instruction in midwifery. A lady announced that she had got a promise of £1000 provided the ladies themselves raised £2000. The ladies should aim at building a completely new up-to-date maternity hospital in Belfast.

The Public Health Committee of the Belfast City Council.

The City Council of Belfast have beaten all previous records for lengthened sittings. The November meeting began on the first day of the month and was devoted to the question of tramway extensions; the next day was all spent in an acrimonious discussion on the new city hall; while the most important question of public health was, as one of the

Digitized by Google

members of the council complained, relegated to the tail end of the agenda, and only came up on the third day, when the corporate fathers were thoroughly sick of the prolonged discussions of the two previous days. From the report of the medical superintendent it is seen that between Sept. 18th and Oct. 15th, 1898, the number of cases of typhoid fever notified was 636. The deaths from zymotic diseases were 191, while in the corresponding period of last year there were 76 deaths from zymotic diseases. The death-rate was 28·3 per 1000, while in the corresponding four weeks of last year it was 21·6. The death-rate from zymotic diseases was 8·2, while in the same period of last year it was 3·5. The chairman of the Public Health Committee was not present, but in his absence the vice-chairman said the outbreak of typhoid fever had been reduced within rather narrow limits, there having been only 8 fatal cases reported during the week. He also made an attack on "black sheep" in the medical profession for notifying cases of typhoid fever which they had never seen, but Councillor Browne, M.D., said he was sorry that some members of the medical profession had been referred to in such terms. He stated that not a single notification had been wrongly entered except in one instance, and that case he dared to say was a mistake on the part of the gentleman who was responsible for it. The latest returns of cases of typhoid fever notified during the week ended Oct. 29th were 98, as compared with 125, 149, 151, 172, 164, and 247 in the previous six weeks. It would appear that fees to the extent of £366 3*s.* 6d. were paid during the past three months for notifications and £1041 0*s.* 9*d.* were spent in disinfectants. I am very glad to be able to report that the typhoid fever outbreak is distinctly diminishing, but it is thought to be due to the prevalence of cold weather and the heavy rainfall and probably the putting of disinfectants down the drains is of very little service. To be sure, it looks as if something was being done, but why not grapple with the real difficulty—that is, have the sewers properly cleaned out—or have a complete new main drainage system, the present being admitted on all hands to be a complete failure? It does not even prevent flooding of certain parts of the city in heavy rains. Very possibly there is a good deal of truth in what Councillor O'Connell, M.D., a member of the Public Health Committee, stated in reference to Belfast, "It would be necessary to begin at the houses and end at the very efflux of the sewerage. This must be done, even if it did cost a lot of money"; and Alderman Lawther was quite correct when he said they would in future have to tackle the serious question of making the sewerage system of the city equal to its population, and if they wanted to keep pace with the growth of the city they must deal with the question of the sewerage of the future. The real risk is that once the typhoid fever scare is over the sanitary reformers in the corporation may be defeated in their most laudable efforts to introduce those reforms so absolutely necessary in Belfast.

Medical Men and Affidavits.

A curious case, of great interest to medical men holding public appointments, came before the Belfast Recorder on Nov. 7th in the local bankruptcy court in reference to the discharge of a man from the Belfast District Asylum. Affidavits made by Dr. W. Graham, resident medical superintendent of the asylum, and by the assistant, Dr. Patrick, to the effect that the man was now of sound mind and able to look after his own affairs, were read. Dr. Graham, in answer to his Honour the Recorder, said he was a public officer paid by the Government and that he had stated that his fee for giving an affidavit would be 3 guineas, and that his attending there (in court) would incur additional expense. His Honour said he had no right to demand anything and that it was his duty to attend there in court and make an affidavit stating the condition of the lunatic, that duty being paid for by the Government. Dr. Graham stated, in reply, he was only asking for what he would get in other courts. He had been a medical superintendent of asylums for ten years and he was only asking for what he received in his former county (Armagh). If he went to the prison, the Prison Board gave him 2 guineas; if he went to the military barracks he got 1 guinea; and the postal authority gave him 2 guineas. The present was the only case in which he had been asked to make an affidavit without a fee. He said he would be glad if the Recorder would communicate with the authorities in Dublin Castle (Dr. Graham's superiors), and inquire of them—he would be guided by their ruling—if he was asking for anything that was not customary, or getting anything to which they objected. The Recorder said this was a matter that he had nothing to do with. Dr. Graham's predecessor did not make such charges and he would follow his practice until he was controlled by a higher authority.

Nov. 8th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The Treatment of Aneurysm by Injections of Gelatinised Serum.

IN THE LANCET of Oct. 22nd the communication of M. Lancereaux to the Academy of Medicine on the employment of gelatinised serum as a method of treating aneurysm of the aorta was published. At the same meeting Dr. Huchard opposed this treatment upon certain grounds. At the meeting of the Academy held on Oct. 24th Dr. Huchard returned to the charge and reported another case of death after this treatment in addition to the one he had mentioned before. According to him there is great risk of the coagulation produced by this method extending too far and being brought about too quickly; the gelatinised serum should be very weak—not more than 1 in 100; a stronger solution is apt to act too quickly and to be followed by a rise in temperature. Finally, at the meeting held on Oct. 31st M. Laborde pointed out that ordinary commercial gelatin, which, he supposed, M. Lancereaux used, is not entirely soluble. Its solutions always contain undissolved particles which, when injected act as foreign bodies and act as foci of coagulation. It is therefore not to be wondered at that these particles once introduced into the circulation should bring about coagulation in vessels more or less distant from the aneurysmal sac and thus bring about results which considerably discount the benefits of M. Lancereaux's treatment. The possibility of such accidents is by no means imaginary. They had been brought about experimentally after intravenous injection of the serum; more than that they had occurred in practice, as Dr. Huchard had shown at the preceding meeting. As it is obvious that gelatin does exercise a coagulative action the method is sound fundamentally, but it must be used with the very greatest care. The injection should be made into the aneurysmal sac itself or, failing that, as near to it as possible, absorption in the latter case being rapid owing to the development of the circulation in the vicinity of the aneurysm.

Obstinate Constipation relieved by Massage of the Hepatic Region.

At the meeting of the Academy of Medicine held on Oct. 31st M. Berne read a paper on a case of obstinate constipation occurring in a little girl, aged three and a half years, who had previously suffered from chronic muco-membranous entero-colitis. No drugs were found to be of any use and the condition eventually yielded to massage. On the eleventh day of treatment natural motions were passed, the patient's condition gradually improved, and by the thirteenth day the motions became quite regular, a condition which has lasted up to the present time. M. Berne considers that massage is a most useful method of treatment in cases of obstinate constipation, especially when employed in the region of the gall-bladder. Massage restricted to this region will relieve those cases of constipation which are accompanied by a deficient secretion of bile, and has the additional advantage that it can be performed in the cases of such patients as are unable to bear general massage. For instance, in a patient suffering from an abdominal tumour massage of the hepatic region will cause no discomfort unless, indeed, the tumour be in the hepatic region. Apart from constipation the method is useful in all cases of deficient biliary secretion.

The Surgical Treatment of Adherent Pericardium.

This treatment consists in the division or destruction of the adhesions. At the meeting of the Society of Surgery held on Oct. 26th M. Delorme mentioned that he thought of applying to cases of adherent pericardium the same treatment which he had devised for similar conditions occurring in the lungs. Functional troubles occurring in adherent pericardium are enough to enable a diagnosis to be made.

Digitized by Google

The complications accompanying this condition are exceedingly grave and very common; they include hypertrophy and dilatation of the heart, failing nutrition of the cardiac muscle, valvular troubles, and stenosis of the large vessels. Separation of the adhesions is often very difficult, especially in those patients of advanced age, so that the field for operation is practically limited to the young, who have greater resistant powers. The opening is made at the level of the fifth intercostal space. The pericardium is incised and the parietal layer being raised the right border of the heart is first freed, the operator working towards the lower border. It is necessary to stop at the level of the auricle, for the walls of this cavity are too thin to bear manipulation. The bands are divided either by the finger or by cutting.

Medical Aid and the Army.

The Minister of War has just taken a step which has been sharply criticised by the whole medical press. It has recently been decided that workmen employed in the military workshops at Toulouse should be entitled to free medical aid for themselves and their families. The Minister therefore applied to the medical men and midwives of the town, and in order to carry out his views as cheaply as possible he put up the office to auction in a way. Notices were posted up saying that medical men desirous of being employed in this manner should send in their names and the fee they should demand, either per case or by a yearly subscription. Preference, it was intimated, would be given to the lowest tender. This is the first time that a public body has sought to impose such humiliating conditions upon medical men—not even the clubs have hitherto done such a thing.

Dr. Lucas Championnière and the Prince of Wales's Fracture.

In an article in his own paper, the *Journal de Médecine et de Chirurgies Pratiques* of Oct. 25th, Dr. Lucas Championnière answers those who have criticised in the English press his opinions on fracture of the patella and his criticism on the way in which the Prince of Wales has been treated. He held to all his opinions as to the doing without an immobilising apparatus, which he considers harmful, and also as to the superiority of treatment by opening the joint and massage. He brings forward a case of complete cure which occurred in a little village of the Alps where the patient, a female, who had a very bad fracture, was massaged by her servant and had no surgical treatment whatever except advice from a military surgeon who happened to be passing through the district that day to take part in some military manœuvres. Dr. Lucas Championnière complains that some critics in certain English papers have made this a personal and international question, whereas for his part he only wished to look at it from a scientific point of view and in support of the trust which is put in this method of treatment outside France where it has very quickly become popular.

The Case of Dr. Boisleux and Dr. La Jarrige.

These two medical men, who were condemned about eighteen months ago on a charge of procuring abortion, have been set at liberty. Dr. Boisleux was working out his sentence in the prison at Étampes, where he had already attempted suicide twice. He considers he was in danger of getting general paralysis. The common report is that he will no longer practice as a medical man but is going to become a member of a large firm of surgical instrument-makers. Dr. La Jarrige, who is a brother of a general who some time ago retired from the service and died from grief, was placed in a *maison de santé* at Versailles on the plea of morbus cordis. After being set free he returned to Montreuil, close to Paris, where he practised formerly, and where he intends to continue, as everybody manifests the greatest sympathy for and confidence in him.

Nov. 8th.

ROME.

(FROM OUR OWN CORRESPONDENT.)

Death of the "Father of Seismology."

COUNT MICHELE STEFANO DE ROSSI, who made seismology a science by his work on "telluric storms" and his observatories, and the instruments of his own invention for forecasting the same, died last week in his château at Rocca di Papa in the Agro Romano. He was brother of the equally distinguished Count Giovanni Battista de Rossi, the greatest authority of his time on Christian antiquities, particularly as contained in the Catacombs. Count Michele in 1881 and again in 1883 predicted, weeks before their occurrence, the calamitous earthquakes in Ischia, but his warnings were unheeded by the hotel-keepers or rather kept dark lest they should scare away from the sulphur baths the numerous public which frequents them. With the Padre Denza of the Vatican Observatory, and Professor Luigi Palmieri of the Observatory on Mount Vesuvius, whose deaths in October, 1894, and in September, 1896, respectively, were noticed in THE LANCET, he contributed to earn for Italy the honoured place she holds in that field of Nature-study which concerns itself with the earth's crust.

Malaria Studies.

The Roman school deserves all the praise it received from Professor Koch at the close of his recent visit for its good work in the therapeutics of malaria. On this point Professor Koch bears effective witness. One evening last autumn among the admissions to the clinical wards of the Santo Spirito Hospital he saw a patient in the final stage of malaria perniciosa. Anticipating the man's death in a few hours he bespoke the body so as to proceed to the necropsy with the least loss of time. The request, as usual, was courteously granted and next morning Professor Koch appeared at the Santo Spirito Hospital, expecting to find everything ready for the post-mortem examination. To his astonishment he found the moribund patient of the previous day sitting up in bed, cured. Inquiring as to what had occurred to account for this quasi-resurrection he was told that the man had been at once subjected to the usual treatment in such aggravated cases—the intravenous injection of quinine as proposed and practised years ago by Baccelli—and that the response had been, as it generally was, quite satisfactory. With the chivalry which characterises him he hastened at once to the Ministry of Public Instruction and then and there congratulated Baccelli on the success of his treatment. A few weeks afterwards Baccelli himself, presiding at the Congress of Internal Medicine, repeated the anecdote in the course of an address on the contributions of Italians, not only to the therapeutics, but to the etiology of disease, malaria included. In this latter field they have been working steadily and silently and have obtained results only now becoming known. Profiting by the experience of Laveran, if not by that of Manson and Ross, Dr. Amico Bignami, *privat-docent* in pathological anatomy at the University, had in 1896 by observation and experiment convinced himself that malaria was a "disease of inoculation." The same year, working in concert with Dr. Dionisi, also of the Roman school, he experimented on the possibility of engendering malaria fever by means of the punctures of mosquitoes. Their experiments yielded no positive result, but were repeated in the August and first half of September (still in 1896), once more with a negative response. Dr. Bignami and Dr. Dionisi had failed to satisfy themselves, among the numerous tribes of mosquitoes, as to that one which had relations, mediate or immediate, with malaria. However, Dr. G. B. Grassi, Ordinary Professor of Comparative Anatomy, whose work in illustration and reinforcement of the Darwinian induction was rewarded two years ago by the Royal Society of London, succeeded last summer in completing a series of observations by which he ascertained and determined the mosquito tribes which had power to convey the disease. Italian medicine, already distinguished in the malarial field by the studies of Tommasi-Crudeli, Baccelli, Golgi, Celli, Marchiafava, and others, chiefly of the Roman school, expects to establish a claim to having made out the special tribes of malaria-conducting mosquitoes—tribes three in number and found exclusively in the fever-infected localities. I am further informed that Dr. Dionisi has discovered in bats a malaria-infection due to parasites olosely resembling those found in the blood of malarious man. Here, again, a new field for observation opens up. Professor Koch, indeed, on his return to Rome next spring for the further prosecution of his researches, will find no lack of material provided by Italian colleagues for the checking or confirming of the conclusions at which he has provisionally arrived.

Nov. 7th.

Medical News.

APOTHECARIES' HALL OF IRELAND.—The following candidates passed in the First, Second, and Third Professional Examinations at the October examinations:—

Physics.—William Long.
Chemistry (including Theoretical and Practical).—Henry T. De Blacquiere.
Biology.—Henry T. De Blacquiere.
Second Anatomy.—John Thompson.
Physiology (including Histology).—John Thompson.
Hygiene.—M. A. O'Carroll.
Pathology.—M. A. O'Carroll.
Mr. John Thompson has completed the Second Professional Examination.

CONJOINT EXAMINATIONS IN IRELAND BY THE ROYAL COLLEGE OF PHYSICIANS OF IRELAND AND THE ROYAL COLLEGE OF SURGEONS IN IRELAND.—The following candidates have been successful in the examinations for the diploma in State Medicine and Public Health:—

Honours Division.—W. M. H. Spiller, M.B., and H. K. Abbott, M.D.
Pass Division.—J. J. Brownlee, M.D., R. Cheyne, L.S.A., L.R.C.P. Edin., J. E. Dods, M.B. Edin., and J. G. Shea, F.R.C.S. Irel.

FOREIGN UNIVERSITY INTELLIGENCE.—*Vienna:* Professor Knoll of Prague has been appointed to the chair of Experimental Pathology vacant by the death of Professor Stricker.—*Breslau:* A new Anatomical Institute has just been opened. It is under the direction of Professor Hasse.—*Erlangen:* Dr. Friedrich Schneider has been appointed to give instruction in Odontology. — *Lausanne:* Professor Bourget has been appointed Director of the Medical Clinic and Professor Rabow has succeeded to the chair of Pharmacology.

ROYAL COLLEGE OF PHYSICIANS OF IRELAND.—At the monthly meeting of the President and Fellows held on Nov. 4th, Mr. Henry Jellett, M.D. Dub., was admitted to the Fellowship of the College.

UNIVERSITY COLLEGE OF WALES.—The annual meeting of the Court of University College of Wales was held at the University College, Aberystwyth, on Nov. 3rd, under the presidency of Dr. Isambard Owen, the senior deputy chancellor. The Registrar reported that the number of candidates who entered the matriculation examination was 430, being 61 in excess of the number for 1897. There were 422 entries of candidates for the degree examination, being 137 in excess of last year. The congregation for the admission to degrees was afterwards held.

SALFORD ROYAL HOSPITAL.—The annual meeting of the Salford Royal Hospital was held on Oct. 26th. The number of patients treated in the hospital at the Pendleton Branch Dispensary during the year was 26,776, against 25,024 in 1897 and 25,558 in 1896. The officers of the District Provident and Charity Organisation Society had inquired into the circumstances of 12,685 applicants for medical relief and reported that 459 were in a position to obtain medical relief through the provident dispensaries or to pay for private attendance. The income for the year was £5447, rather more than that of the previous year, and the expenditure was £6477. There was a slight falling off in the annual subscriptions and the number of subscribers was given as 432, a very small proportion of the population of the borough. The lists of subscribers to the various charities in both Manchester and Salford show that giving is confined to the few. Though there are many wealthy people connected with Salford the majority of those living in the town itself may be called comparatively poor, yet a large proportion could give small sums and probably would be glad to do so if it were made easy for them, but they do not like their names with their small contributions to appear as a contrast to the larger sums given by their richer neighbours. The board thanked the promoters of the Manchester and Salford Cyclists' and Harriers' Charity Parade for the handsome contribution of £344 11*s.* 9*d.*, being the amount collected at the parade in September last. During the year the electric light has been introduced and efficient telephonic intercommunication established throughout the hospital. The medical report told of increasing work and the urgent need for more accommodation, especially for surgical cases. The Dean of Manchester suggested the advisability of asking various football clubs to devote the "gates" at some of their matches towards the funds of the hospital.

MEDICAL TOWN COUNCILLORS.—Mr. Paul Swain, F.R.C.S. Eng., has been elected a member of the Town Council for Plymouth. Mr. John Grant Wilson, M.R.C.S. Eng., L.S.A., J.P., has been returned for Monmouth.

BICYCLES FOR NURSES.—The Managers of the Doncaster Infirmary have already provided one bicycle for the use of the nurses during recreation hours and have now opened a subscription for another "wheel" for the nurses' use.

LITERARY INTELLIGENCE. — *The Medical and Surgical Review of Reviews*, a monthly magazine edited by Mr. Nathan E. Boyd, M.D., and published at Connaught Mansions, S.W., is a publication on the lines of Mr. Stead's well-known journal, but deals of course exclusively with medical and cognate subjects. The first number was published last month. As a guide to current medical literature the new *Review of Reviews* will be found extremely useful to busy practitioners and more especially with regard to foreign publications.

FREEMASONRY.—*The Rahere Lodge, No. 2546:* An emergency meeting of this lodge was held at Frascati's Restaurant on Tuesday, Nov. 8th, Bro. Burns, W.M., in the chair. Messrs. Coventon, Tucker, Gay, and Griffiths were elected members of the lodge and were initiated into Freemasonry. Dr. Roberts was elected a member, and Bro. A. M. Jackson, M.D. Oxon., was elected a joining member. Bros. Folliott, Christopherson, Mackintosh, Briggs, and Keats were admitted to the third degree. The brethren and their guests afterwards dined together.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. Theodor Gsell-Fels, the well-known writer of handbooks for travellers, has died in Munich at the age of seventy-nine. He was Doctor of Medicine, of Philosophy, and of Theology, and published several scientific works on Balneology and Climatology, the best known of which, perhaps, is his "Baths of Switzerland."—Dr. Wilhelm Kochs, Docent of Physiology in the University of Bonn. He had published several researches on the physiology of the nerves and of respiration. His age was thirty-six. — Dr. Ewald Geissler of Dresden, one of the authors of the "Real-Encyclopädie der Pharmacie."—Dr. Bouchacourt, formerly Professor of Midwifery in the Medical Faculty of Lyons.—Dr. Morrison, formerly Professor of Physiology in Nashville, U.S.A.

PRESENTATIONS TO MEDICAL MEN.—On Oct. 28th Mr. T. J. Vallance, M.D. St. And., who recently resigned the post of medical officer to the West Ham Union Workhouse, was entertained to a complimentary dinner at the Langthorne Rooms by nearly forty of the officers connected with the union. Mr. W. A. Grogono, one of the senior medical officers, presided. In proposing the health of Dr. Vallance he remarked that his appointment as medical officer to the workhouse dated back as far as 1867 and during the whole of his thirty-two years' service he had been conscientious, kindly, and in good fellowship with his fellow workers, and on behalf of all the officers he had great pleasure in presenting Dr. Vallance with a liqueur stand, which bears the following inscription: "Presented to Dr. T. J. Vallance by the officers of the West Ham Union as a mark of their high appreciation and esteem on his retirement as medical officer after 32 years' service."—The occasion of the resignation of Mr. John Rees James, M.R.C.S. Eng., L.S.A., medical officer of the second district of the Neath Union and surgeon to the Cwmavon Copper Works, was taken advantage of by the inhabitants of the district to present him with a testimonial in recognition of his twenty-eight years' residence amongst them. The presentation consisted of three massive silver salvers, suitably inscribed, a purse of gold, and a pearl and ruby bracelet for Mrs. James.—Last week the Mayor of Swansea presented certificates to the successful candidates in connexion with the London and North-Western Railway (Swansea branch) of the St. John Ambulance Association and afterwards presented Mr. Edgar Reid, L.R.C.P. Lond., M.R.C.S. Eng., with an aneroid barometer as a mark of appreciation for his services as honorary lecturer to the class.

UNIVERSITY COLLEGE, LONDON.—Mr. Swale Vincent, M.B. Lond., M.R.C.S. Eng., has been elected to the Sharpey Physiological Scholarship (£150 per annum), which carries with it the post of chief assistant in the physiological laboratory. Mr. D. J. Armour, M.B., M.R.C.P., has been appointed to the vacant demonstratorship in anatomy.

DIPHTHERIA IN LONDON.—For the four weeks ended on Oct. 8th the notified cases of diphtheria in the county of London numbered 1039, a notable increase on the 699 notifications of the similar period ended on Sept. 10th, for the average number of 175 notified cases weekly of the earlier period rose to a weekly average of 260, the excess of the October period being in this way markedly shown. In the September period all the sanitary areas were invaded, but not one returned as many as 50 cases, whereas in the October period two sanitary areas escaped attack. Nevertheless, as many as five districts had each of them upwards of fifty attacks, with an aggregate of 346, as against a total of 9 in other five invaded localities. The registered deaths of the September period were 107 in number, giving a case mortality rate of 15·3 per cent., but while the fatal cases registered in the October period increased to 125 (or a weekly average of 31, with a minimum of 29 and a maximum of 34), the excessive number of attacks resulted in a decline in the case rate of mortality to 12·0 per cent. In the outer circle the registered deaths from diphtheria in the September period amounted to 39, and reached 50 in the October period, the weekly data being 11, 12, 17, and 10 respectively, of which 8, 6, 7, and 6, or 27 in all, belonged to the West Ham registration district. In the completed weeks that have since elapsed, the weekly deaths from diphtheria registered in the county of London have been 41, 30, 46, and 28, or 145 in all. In the outer circle the registered deaths have been 6, 9, 19, and 17, or 51 in all.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, for publication in the next number.*

BEATTIE, JAMES M., M.A. New Zealand, M.B., C.M. Edin., has been appointed Assistant to the Professor of Pathology, University of Edinburgh.

BEGGS, S. T., M.B., B.Ch. Irel., has been appointed a Demonstrator of Physiology, Queen's College, Belfast.

BENNETT, W. B., L.R.C.P. Lond., M.R.C.S., has been appointed an Assistant Medical Officer for the Workhouse of the parish of Liverpool.

CANDLER, J., M.R.C.S., has been re-appointed Medical Officer of Health by the Depwade Rural District Council.

COLE, J. W. E., L.R.C.P. Lond., M.R.C.S, has been appointed an Assistant Medical Officer for the Bow Infirmary.

EVANS, H. M., M.D. Lond., L.R.C.P., M.R.C.S., has been appointed an Assistant Surgeon for the Lowestoft Hospital.

EVISON, F. A., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer for the Second Sanitary District of the North Witchford Union, vice F. O'Conner.

GODSON, J. H., M.B., B.C. Cantab., has been re-appointed Medical Officer of Health by the Cheadle and Gatley Urban District Council.

HEPBURN, M. L., M.D. Lond., B.S., L.R.C.P., F.R.C.S. Eng., has been appointed an Assistant Surgeon for the Lowestoft Hospital.

HERMON, J. M., M.B., C.M. Edin., has been appointed a Medical Officer for the Crofton Sanitary District of the Wakefield Union.

LAVER, P. G., L.R.C.P. Lond., M.R.C.S., has been appointed a Medical Officer for the Colchester Union.

LAW, DR., has been appointed Medical Officer of Health by the Macduff Town Council.

LOVEDAY, W. D., L.R.C.P. Lond., M.R.C.S., has been appointed a Medical Officer for the Hundred Sanitary District of the Wantage Union.

MACEWEN, WM., M.D., C.M. Glasg., F.F.P.S., has been appointed a Corresponding Member of the Royal Medical Academy of Rome.

MAJOR, HERBERT C., M.D. Edin., has been appointed a Consulting Physician to the Bradford Royal Infirmary.

MORSE, EDWARD, L.R.C.P., L.R.C.S. Edin., has been re-appointed Medical Officer of Health for Great Torrington.

PROCTER, G. L., M.B., C.M. Edin., has been appointed Medical Officer for the Dawley Sanitary District of the Madeley Union, vice C. B. H. Soame, resigned.

RICHARDS, H. M., M.D. Lond., L.R.C.P., M.R.C.S., has been appointed Medical Officer of Health by the Dronfield Urban District Council.

ROBERTS, R. W., L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., has been appointed Medical Officer or Health for the Cwmavon Sanitary District of the Neath Union.

SCHOLEFIELD, GEORGE E., M.D., D.P.H., has been appointed Medical Officer of Health to the West Lancashire Rural District Council, vice H. Peck.

SEQUEIRA, J. H., M.D. Lond., M.R.C.P., F.R.C.S. Eng., has been appointed Physician to the Tower Hamlets Dispensary, vice H. B. Donkin, resigned.

SIMPSON, G. A. G., M.R.C.S., has been re-appointed Medical Officer of Health by the Acton Urban District Council.

STARLING, E. H., M.D. Lond., B.S., F.R.C.P., M.R.C.S., has been appointed an Examiner in Physiology at the University of Cambridge.

TYSON, W., L.R.C.P. Lond., M.R.C.S., has been appointed an Assistant Surgeon for the Lowestoft Hospital.

WILLIAMS, J. H., M.D., C.M. Edin., has been re-appointed Medical Officer of Health by the Flint Urban District Council.

Vacancies.

For further Information regarding each vacancy reference should be made to the advertisement (see Index).

BIRMINGHAM PROVIDENT DISPENSARY (SANDS COX TRUST), HOCKLEY BRANCH.—Medical Officer. Salary in proportion to the number of members, with a minimum of £250 per annum and residence.

BRADFORD ROYAL INFIRMARY.—House Physician, unmarried. Salary £100 per annum, with board and residence. Also Dispensary Surgeon, unmarried. Salary £100 per annum, with board and residence. Also Junior House Surgeon, unmarried. Salary £50 per annum, with board and residence.

CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST, Victoria-park, E.—House Physician for six months. Salary at the rate of £30 per annum, with board and residence.

DARLINGTON HOSPITAL AND DISPENSARY.—House Surgeon, unmarried. Salary £140 per annum, with lodging. Appointee to board himself.

DERBY COUNTY ASYLUM, Derby.—Assistant Medical Officer, unmarried. Salary £100 per annum, rising to £120, with board, lodging, and washing.

DUNDEE ROYAL LUNATIC ASYLUM.—Medical Assistant. Salary £100, with board and lodging.

EAST LONDON HOSPITAL FOR CHILDREN AND DISPENSARY FOR WOMEN, Shadwell, E.—Assistant Physician.

EVELINA HOSPITAL FOR SICK CHILDREN, Southwark-bridge-road, S.E.—Junior Resident Medical Officer and Registrar. Salary £50, with board and washing.

FINSBURY DISPENSARY, Brewer-street, Goswell-road, E.C.—Resident Medical Officer for one year. Salary £100 per annum, and a furnished residence provided in the institution, with attendance, coals, and gas.

GENERAL HOSPITAL, Birmingham.—House Surgeon for six months. Residence, board, and washing provided.

GLAMORGAN COUNTY COUNCIL.—Bacteriologist to work in the Council's Laboratory at Cardiff. Salary £250 a year. No pension is attached. Applications to the Clerk to the County Council, Glamorgan County Offices, Cardiff.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, Bloomsbury, London.—House Surgeon for six months. Unmarried. Salary £20, with board and residence in the hospital. Also House Physician for six months. Salary £20, with board and residence in the hospital. Also Assistant Surgeon.

LIVERPOOL DISPENSARIES, 34, Moorfields, Liverpool.—Assistant Surgeon. Salary £80, rising to £90 per annum after the first years' service, with board and residence.

LONDON HOSPITAL, Whitechapel, E.—Assistant Surgeon. Also Medical Registrarship.

LONDON LOCK HOSPITAL, 91, Dean-street, Soho, W.—House Surgeon for the Male Hospital. Salary £50 per annum, with board, lodging, and washing. Applications to the Secretary at Harrow-road, Paddington, W.

MANCHESTER ROYAL INFIRMARY.—Resident Medical Officer for the Convalescent Hospital at Cheadle for twelve months, unmarried. Salary £150, with board and residence.

MASON UNIVERSITY COLLEGE, Birmingham.—Lecturer on Osteology and Chief Demonstrator of Anatomy.

METROPOLITAN HOSPITAL, Kingsland-road, N.E. — Anæsthetist. Honorarium 25 guineas per annum.

NEWCASTLE-ON-TYNE DISPENSARY.—Two Visiting Medical Assistants for one year at least. Salary £120 for first year and £150 afterwards.

NORFOLK COUNTY ASYLUM, Thorpe, Norwich.—Junior Assistant Medical Officer, unmarried. Salary £110 per annum, with £10 annual increase, with board, lodging, and washing.

Digitized by Google

NORTH-EASTERN HOSPITAL FOR CHILDREN, Hackney-road, Shoreditch.—House Surgeon for six months. Salary at the rate of £50 per annum, with board and washing. Applications to the Secretary, City Office, 27, Clement's-lane, Lombard-street, E.C.

NORTHUMBERLAND COUNTY ASYLUM, Morpeth.—Assistant Medical Officer, unmarried. Salary £125 per annum, rising £10 yearly to £155, with board, lodging, and washing.

PARISH OF ST. JOHN, Hampstead.—Workhouse Medical Officer. Salary £150 per annum, and extra fees value about £40 per annum, subject to statutory reduction. Applications to the Clerk, Guardians' Offices, New End, Hampstead, N.W.

ROTHERHAM HOSPITAL AND DISPENSARY.—Assistant House Surgeon. Salary £40 per annum, with board, washing, and residence.

ROYAL HOSPITAL FOR DISEASES OF THE CHEST, City-road, London.—Resident Medical Officer for six months. Salary at the rate of £100 per annum, with furnished apartments, board, and washing.

ROYAL ORTHOPÆDIC HOSPITAL, 297, Oxford-street, and 26, Hanover-square, London.—House Surgeon and Anæsthetist for six months. Unmarried. Salary at the rate of £100 per annum, with residence and partial board.

ROYAL WESTMINSTER OPHTHALMIC HOSPITAL, King William-street, West Strand, W.C.—Assistant Surgeon. Also Clinical Assistants, to be held for six months.

ST. PETER'S HOSPITAL, Henrietta-street, Covent Garden, London.—House Surgeon for six months. Salary at the rate of £100 a year, with board, lodging, and washing.

SEAMEN'S HOSPITAL SOCIETY (*Dreadnought*), Greenwich.—House Surgeon for Branch Hospital, Royal Victoria and Albert Docks, E. Salary £50 per annum, with board and residence.

SHEFFIELD ROYAL HOSPITAL.—Resident Junior Assistant House Surgeon. Salary £50 per annum, with board and washing.

STAFFORDSHIRE COUNTY COUNCIL.—Medical Superintendent for the Staffordshire County Asylum at Cheddington. The salary will commence at £500 per annum, with £200 in lieu of board. The asylum is not yet completed, and the successful candidate is to reside at the residence provided. In addition to the above salary the emoluments include a partly furnished residence, &c.—Applications to the Clerk to the Council, Stafford.

VICTORIA HOSPITAL FOR CHILDREN, Queen's-road, Chelsea, S.W.—Assistant Physician for the Out-patients for two years.

WEST BROMWICH DISTRICT HOSPITAL.—Resident Assistant House Surgeon for six months. Gratuity £20, and board, lodging, and washing in the hospital.

WESTMINSTER HOSPITAL, Broad Sanctuary, S.W.—Fourth Assistant Physician.

WHITEHAVEN AND WEST CUMBERLAND INFIRMARY.—House Surgeon. Salary £120 per year, and £30 a year for Dispensing, with furnished apartment and attendance.

Births, Marriages, and Deaths.

BIRTHS.

BRAND.—On Nov. 3rd, at Driffield, E. Yorks., the wife of Dr. Brand of a daughter.

JACKSON.—On Nov. 4th, at Winchmore-hill, Middlesex, the wife of John W. Jackson, F.R.C.P., M.R.C.S., of a daughter.

LUMSDEN.—On Nov. 4th, at Lower Leeson-street, Dublin, the wife of J. Lumsden, M.D., of a daughter.

SANSOM.—On Nov. 6th, at West-end-lane, West Hampstead, N.W., the wife of H. Arthur Sansom, M.D. Lond., &c., of a daughter.

YOUNG.—On Wednesday, Nov. 4th, at 45, Stamford-hill, the wife of John Young, M.D., B.S. Lond., of a daughter.

MARRIAGE.

GARDE—BURROWS.—On Nov. 2nd, at the Church of the Holy Cross, Crediton, Walter Henry Ormond Garde, Surgeon, Royal Navy, to Ethel, youngest daughter of the late Surgeon-Major H. P. Burrows, Bombay Staff Corps.

DEATHS.

BARRY.—On Oct. 21st, 1898, at 10, Brompton-square, London, S.W., Julia, the dearly beloved wife of W. J. M. Barry, M.D., M.R.C.P. Requiescat in pace.

HACON.—On Tuesday, Sept. 20th, at Christchurch, New Zealand, suddenly from apoplexy, Walter Edward Hacon, M.R.C.S., L.R.C.P., L.S.A. Lond., aged 47 years, only surviving son of Edward D. Hacon, F.R.C.S., of Hackney, Middlesex.

PENNINGTON.—On Nov. 4th, at Lugano, Brigade-Surgeon Frederick Pennington, aged 68.

WOODHAMS.—On Nov. 3rd, suddenly, at Park-place, Gravesend, Sidney Woodhams, M.R.C.S., L.R.C.P. Lond., aged 34.

WYATT.—On Nov. 7th, at his residence, Clissolds, Shelly-road, Worthing, William Thomas Wyatt, M.A., M.D. Oxon., aged 44.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Medical Diary for the ensuing Week.

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (14th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M., Ophthalmic 1.15 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), St. Mark's (9.30 A.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), Royal Orthopædic (2 P.M.), City Orthopædic (4 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), Westminster (2 P.M.), London Throat Hospital (2 P.M.).

TUESDAY (15th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), Guy's (1.30 P.M.), St. Thomas's (3.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.), Metropolitan (2.30 P.M.), London Throat Hospital (2 P.M. and 6 P.M.), Royal Ear Hospital (3 P.M.).

WEDNESDAY (16th).—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), King's College (2 P.M.), St. Mary's (2 P.M.), National Orthopædic (10 A.M.), St. Peter's (2 P.M.), Samaritan (2.30 P.M.), Gt. Ormond-street (9.30 A.M.), Gt. Northern Central (2.30 P.M.), Westminster (2 P.M.), Metropolitan (2.30 P.M.), London Throat Hospital (2 P.M.).

THURSDAY (17th).—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), University College (2 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (1.30 P.M.), St. Mary's (2.30 P.M.), Soho-square (2 P.M.), North-West London (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (Gynæcological, 2.30 P.M.), Metropolitan (2.30 P.M.), London Throat (2 P.M.).

FRIDAY (18th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M., Ophthalmic 10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat Hospital (2 P.M. and 6 P.M.).

SATURDAY (19th).—Royal Free (9 A.M. and 2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), University College (9.15 A.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), St. Mary's (10 P.M.), Cancer (2 P.M.), London Throat Hospital (2 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

SOCIETIES.

MONDAY (14th).—MEDICAL SOCIETY OF LONDON.—8.30 P.M. Clinical Cases:—The President: A Patient after Gastro-enterostomy performed for Pyloric Obstruction.—Mr. Openshaw: Excision of the Larynx.—Dr. H. Mackenzie: Vascular Murmur of Obscure Origin audible at the Base of the Right Lung.—Dr. S. Taylor: Aneurysm of the Right Carotid.—Dr. Hadley: Diabetes Insipidus.—Mr. Battle: (1) Recovery from Sarcoma treated after Coley's Method; (2) Genu Retrorsum; (3) Hepatoproptosis; (4) a Patient with Three Patellæ.

TUESDAY (15th).—PATHOLOGICAL SOCIETY OF LONDON.—8.30 P.M. Mr. T. Carwardine: Tumour of the Rectum.—Dr. W. Hunter: Thrombus on the Breast with Embolism of the Common Iliac Artery in the course of Enteric Fever.—Prof. J. R. Bradford: Carcinoma of the Gall Bladder without Gall Stones.—Dr. W. Hadley: Intrathoracic Sarcoma.—Dr. A. C. Latham: Multiple Abdominal Dermoids.—Dr. Freyberger: Embolism of both Middle Cerebral Arteries. Card Specimens by Dr. W. Hunter (Carcinoma of Gall Bladder) and Dr. Rolleston.

WEDNESDAY (16th).—ROYAL MICROSCOPICAL SOCIETY (20, Hanover-square, W.).—7.30 P.M. Exhibition of Thum's Slides of Diatoms mounted in High Refractive Media.

ROYAL METEOROLOGICAL SOCIETY (Institution of Civil Engineers, Gt. George-street, Westminster, S.W.).—7.30 P.M. Papers:—By the Wind Force Committee: Report on Experiments upon the Exposure of Anemometers at Different Elevations.—Capt. D. Wilson-Barker: Comparison of Estimated Wind Force with that given by Anemometers.—Mr. W. Marriott: The Tornado at Camberwell, Oct. 29th, 1898.

THURSDAY (17th).—HARVEIAN SOCIETY OF LONDON (Stafford Rooms, Titchbourne-street, Edgware-road).—8.30 P.M. Dr. St. C. Thomson: Functional Dysphagia.

SOCIETY OF ANÆSTHETISTS (20, Hanover-square, W.).—8.30 P.M. Paper:—Prof. Ramsay: Pure Anæsthetics.

FRIDAY (18th).—CHARITY ORGANISATION SOCIETY (Portman Rooms, Baker-street, W.).—4.30 P.M. Dr. Rayner: The Lunatic Asylum. (Course of Lectures on Medical Relief.)

EPIDEMIOLOGICAL SOCIETY OF LONDON (11, Chandos-street, Cavendish-square, W.).—8.30 P.M. Dr. F. Parsons: Half a Century of Sanitary Progress and its Results. (Presidential Address.)

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

MONDAY (14th).—LONDON POST-GRADUATE COURSE.—London Throat Hospital, Gt. Portland-st., W., 8 P.M., Dr. H. Tilley: Demonstration of Selected Cases (Ear, Throat, and Nose).

TUESDAY (15th).—NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC (Queen-sq., W.C.).—3.30 P.M. Sir W. Gowers: Degenerative Diseases of the Nervous System in relation to Causation.

WEST-END HOSPITAL FOR DISEASES OF THE NERVOUS SYSTEM (73, Welbeck-street, W.).—4 P.M. Mr. J. Cantlie: Cases illustrating the Surgery of the Brain.

LONDON POST-GRADUATE COURSE.—Hospital for Skin Diseases, Blackfriars, 4.30 P.M., Dr. P. Abraham: Scabies.—Bethlem Hospital, 2 P.M., Dr. Craig: General Paralysis.

THE LONDON SKIN HOSPITAL (40, Fitzroy-square, W.).—4 P.M. Mr. A. Harbord: Syphilis—Treatment.

WEDNESDAY (16th).—HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST (Brompton).—4 P.M. Dr. Green: The Symptomatic Treatment of Pulmonary Tuberculosis.

LONDON POST-GRADUATE COURSE.—Parkes Museum, Margaret-st., W., 4.30 P.M., Prof. A. Wynter Blyth: Air.

Digitized by Google

WEST LONDON POST-GRADUATE COURSE (West London Hospital, W.).—5 P.M. Dr. W. A. Turner: The Methods of applying Electricity in Medicine.

THURSDAY (17th).—ROYAL COLLEGE OF SURGEONS.—3 P.M. Annual Meeting of Members and Fellows.

LONDON POST-GRADUATE COURSE. — Central London Sick Asylum Cleveland-st., W., 5.30 P.M., Dr. G. Oliver: The Pulse.

LONDON TEMPERANCE HOSPITAL.—2 P.M. Dr. S. Fenwick: Clinical and Pathological Demonstration to Senior Students.

CHARING-CROSS HOSPITAL.—4 P.M. Dr. A. Routh: Gynæcological Cases. (Post-Graduate Class.)

THE HOSPITAL FOR SICK CHILDREN (Gt. Ormond-street, W.C.).—4 P.M. Dr. Voelcker: Demonstration of Selected Cases.

FRIDAY (18th).—LONDON POST-GRADUATE COURSE.—King's College, 3 to 5 P.M., Prof. Crookshank: Typhoid Fever and Diphtheria.

WEST LONDON POST-GRADUATE COURSE (West London Hospital, W.).—5 P.M. Dr. W. A. Turner: The Methods of applying Electricity in Medicine.

Notes, Short Comments, and Answers to Correspondents.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only, AND, WHEN ACCOMPANIED BY BLOCKS, IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance.

HYPODERMIC INJECTION OF CARBOLIC ACID IN TETANUS.

IN the *Supplemento al Policlinico* of Oct. 15th Dr. Livio Metelli of Cologne Ortano, Brescia, publishes a case of recovery from tetanus under the hypodermic administration of carbolic acid, as suggested by Professor Baccelli. The patient, a farmer, twenty-one years old, complained to him on May 1st of difficulty in swallowing. Ten days before he had sustained a bruise of the right toe, which was healing but still retained visible traces of earth. After a lapse of twelve hours he was found to present the characteristic signs of tetanus—trismus, slight opisthotonos, spasm of the thoracic muscles, and a feeling of suffocation. He perspired profusely, his temperature was 38° C. (100·4° F.), and his pulse was 110. On the third day he had three injections of an ordinary Pravaz syringeful of 4 per cent. carbolic acid solution; this was repeated on the fourth and fifth days; on the sixth day he had in twenty-four hours five injections of a 5 per cent. solution. From that time he began to recover slowly, but the treatment of the sixth day was continued for fifteen days, the administrator being a member of the patient's family. Not the slightest symptom of carbolic acid poisoning was produced, and in fifty days the man was quite well.

SCARLATINIFORM ERUPTION IN INFLUENZA.

To the Editors of THE LANCET.

SIRS,—I have lately attended a large number of cases of influenza of the usual types, but scattered through them, I have also seen some cases with a scarlatiniform eruption which was occasionally followed by desquamation. I shall be most grateful if any of your readers will tell me whether other observers have seen such eruption and desquamation in influenza, and if so what are the points of distinction between this influenzal rash and that of scarlet fever?

I am, Sirs, yours faithfully,

Nov. 7th, 1898. ERUPTION.

EUCALYPTUS GLOBULUS.

A CORRESPONDENT, Dr. Harry Benjafield of Hobart Town, sends us a communication in praise of the virtues of the Eucalyptus globulus. Although Dr. Benjafield is perhaps somewhat too enthusiastic in his praise we print the following extracts from his letter as we think they possess a certain amount of interest.

"..... Although Tasmania is the land where Eucalytus globulus grows everywhere it is the most popular of all remedies. One sees it in the homes of the wealthy citizen, who rubs his gout with the oil and puts it in his baths for any aches and pains he may have and uses it for a hundred other purposes. So much is this the case that the wife of one of our judges told me that in her house it had supplanted nearly all the old household remedies. Again, in the most remote bushman's hut it is invariably seen and he swears by it for pretty nearly every ill that flesh is heir to; if he gets a cold he sniffs it; if a cough he puts it into boiling water and inhales the steam; he rubs in the pure oil for lumbago and for fevers takes it on sugar. For sore legs he uses the green ointment, or failing that binds green leaves on the sore; and I frequently see cases which justify them in their belief. A huge Irishman some two years ago came to me with the smoker's sore on his lower lip as large and thick as a coat-button. As his age, appearance, and pains indicated epithelial cancer I ordered him to have it taken out at once before glandular enlargements made removal useless; and I considered it the more urgent as it had been growing for several months. Some three months after I met him on his cart and pulling him up demanded why he had not been to have it out. 'Begad,' says he, 'look for yourself if it isn't out.' I looked and saw a lip as sound as any lip could be. Then he told me that after leaving me he went to Dr. C——, who also told him he must have it out. Then he thought that before having it out he would try a box of green eucalyptus ointment upon it, and to his astonishment and delight it perfectly healed and the thickening disappeared under its use. To say that I was perfectly nonplussed is saying but little in explanation of my astonishment, as I felt perfectly certain that it was a case of true epithelioma, which I had never before seen disappear under any treatment. Suffice to say that I never now excise such a case without trying this green ointment upon it. ..... M. S., aged four years, who bumped her head against a frying-pan half-full of boiling fat and spilt a great part of it down over her face, ears, and shoulders. I saw her immediately after the accident and found her frightfully burnt, and in a short time the shock to the system produced coma. I made a mask of cotton-wool and soaked it with eucalyptus and olive oil, and enveloped the face, neck, and ears with it. The face rapidly swelled until eyes, mouth, and ears were scarcely visible. By evening the temperature rose to 105°, and coma increased. During the night the nurse, mistaking my directions, poured nearly a pint of pure eucalyptus oil on the dressings, and the following morning the patient was lower in temperature and improved in other ways, still for two or three days she hung between life and death. The eucalyptus and olive oil was the only dressing used and she recovered without a scar on the face and but one on the neck. I have always thought that the nurses' mistake saved the life of the patient."

Dr. Benjafield gives a warning against those purveyors of drugs who sell oil distilled from other varieties of eucalyptus than the globulus. Such oils, he says, are comparatively useless.

A MAN STRUCK BY LIGHTNING ON A RAILWAY TRAIN.

IN the Chicago *Railway Surgeon* of Oct. 4th Dr. C. F. Leslie of Clyde, Kansas, describes a remarkable case. A brakeman on the Missouri Pacific Railway was struck by lightning near Clyde, Kansas, on Aug. 2nd, 1897, and knocked from the brake on the top of a freight car where he was sitting at the time while the train was running at full speed. He was severely burned by lightning on the right side of his chest, on the right hip and buttock, and in the right groin. A

Digitized by Google

handkerchief which he wore about his neck was cut squarely in two and a portion of his watch and chain was melted by the lightning. He fell head foremost from the top of the brake to the ground, a distance of about 14 ft., the momentum due to the speed of the train being added to the fall. When taken up he was insensible and had two scalp wounds. He also sustained, as the symptoms afterwards showed, two distinct fractures of the base of the skull. Blood was running from the nose, mouth, and ears, and was also vomited more or less for thirty hours. The scrotum was nearly torn off, and there was a deep laceration five inches long in the right groin. The tissues here were burned black, would not hold stitches, sloughed in a short time, and subsequently healed by granulation. The scalp wounds and the burns on the body healed in a reasonable time. On the third day the symptoms of concussion had nearly subsided. He then began to take nourishment and to recognise friends, but he was entirely deaf. The hæmorrhage and serous discharge from the ears ceased on the tenth day. He made a good recovery, going back to work on Jan. 1st, 1898.

EMIN PASHA'S MEDICINE CHEST.

WE have received from Messrs. Burroughs, Wellcome and Co. a photograph of a most interesting "Tabloid" Medicine Chest which has just been returned to them by an officer of the Congo Free State, who recovered it from natives near Kenia in the Aruwhimi Dwarf Country. This chest formed the last medical equipment of Emin Pasha, Gordon's Governor of the Equatorial Soudan, and was supplied to him just before he started on his last expedition to Central Africa. The case accompanied him throughout his subsequent travels, and was taken by Arabs after his massacre at Kibungi in October of 1892. After passing through many adventures it was recaptured by Baron Dhanis, commandant of the Congo Free State troops, after the battle of Kasongo, in which the Congo Arabs were defeated. Emin Pasha's journal and a quantity of his property was recovered at the same time, but the "Tabloid" compressed drugs which had been in the chest were found to have been removed. The chest was subsequently stolen by natives and before its final recovery was used as a village treasury chest.

VEGETABLES GROWN ON SEWAGE SLUDGE.

"S. K. P." asks us if vegetables grown in large quantities of sewage sludge are dangerous as human food, and if so, why and to what extent. He makes the inquiry because in his locality the district council have acquired large tracts of land which they are as a matter of economy treating in the following manner. The earth, which is loamy clay, is dug in trenches about 3 ft. deep, into which is conveyed sewage sludge from which some of the liquid has been separated to the depth of about 2½ ft. It is then covered with a mixture of earth and dustbin refuse about 6 in. in depth—that is, until the field has a fairly level surface—and then it is planted with cabbages. He wishes to know if there is any doubt of the wholesomeness of food thus grown.

*** The depth at which the sewage sludge is placed (30 in. beneath the surface) is, we should imagine, too great to allow the cabbages to derive much manurial value therefrom, and also too great to allow of the rapid destruction of the organic matter in the sludge. The danger, if any, from eating cabbages grown in such a way must be entirely neutralised by the cooking to which they are subjected.—ED. L.

THE THERMOPSYCHROPHOR.

THE alternate application of heat and cold to the rectum has been used as a means of treatment in chronic prostatitis, and the thermopsychrophor is an instrument devised for this purpose. It has a tubular stem terminating in an enlargement through which alternate currents of hot and cold water circulate every quarter of a minute. The patterns hitherto in use have some inconveniences, and an improved instrument is described by Dr. Scharff of Stettin in the *Deutsche Medicinische Wochenschrift* of Nov. 3rd. In this pattern the stem is curved at a right angle and is connected to a three-way stopcock by means of a flexible tube surrounded by a wire spiral to prevent it doubling on itself. The other two tubes attached to the stopcock lead each into a reservoir of water of the proper temperature, which may be made to flow through the instrument most conveniently by gravitation, which failing, caoutchouc enema syringes may be used. The tubular stem has a lateral branch to carry away the waste water. The makers are the Medicinisches Waarenhaus, Friedrichstrasse, Berlin.

GONORRHŒA OF THE UTERUS AND ITS APPENDAGES.

IN a paper read before the Philadelphia Medical Society and published in the *Philadelphia Polyclinic* of Oct. 8th Dr. Anna M. Fullerton, of that city, remarks that gonorrhœal inflammation when once established in the vagina usually becomes quite obstinate and is very serious because of its liability to extend to the uterus and its appendages, giving rise to that form of pelvic inflammation which is beyond all comparison the severest. The uterus and appendages may be so changed in structure through the effects of this poison as to be a constant source of ill health. Gynæcologists at first thought it sufficient to remove the appendages when thus diseased, but as the uterus, which had been the avenue of transmission of the poison, was found to be liable to subsequent attacks of inflammation incited by the gonococci and as a uterus without appendages was of no use, the practice came into vogue of removing the uterus as well as the appendages. A strong reaction has of late come about against the total removal of ovaries, but in actual practice the conservation of the ovary has been found to lead to the necessity for numerous secondary operations. As illustrating "the futility of attempting conservative work in at least this class of cases" Dr. Anna Fullerton gives details of 8 patients suffering from gonorrhœal inflammation of the tubes. She removed all the appendages in five instances and one ovary in the sixth.

PROTECTION OF ICE CREAM CONSUMERS.

AT the meeting of the Manchester City Council on Oct. 26th Alderman McDougall adverted to the Corporation Omnibus Bill which was to include the power of framing regulations for preventing the sale of "diseased" milk, and said that in view of the large quantities of milk used in the city for the manufacture of ice cream a clause should be added which would provide that ice cream makers and vendors should be under the same supervision as milk dealers. A resolution in favour of this was passed. In view of the revelations made from time to time of the conditions under which this substance is sometimes concocted, the proposed supervision will not be deemed unnecessary.

Electricity.—"Medical Electricity," by Lewis Jones, M.D., F.R.C.P. (London: H. K. Lewis). This is on the whole the best book on the subject in a small compass. The illustrations representing patients with paralysis of certain muscles or groups of muscles are very valuable. "A Manual of Practical Medical Electricity," by Dawson Turner, M.D., F.R.C.P. Edin. (London: Baillière and Co.), is also a very useful book and contains a chapter on the X Rays. Of larger treatises there are Erb's Treatise in von Ziemssen's Handbook of General Therapeutics, and Beard and Rockwell's Medical and Surgical uses of Electricity. As for apparatus there are many firms, and our correspondent will find no difficulty in selecting one. It would be invidious on our part to particularise.

Izal.—We cannot possibly recommend our correspondent to break the literal wording of his bond. If he agreed not to practise within a radius of a certain number of miles until after the lapse of a certain time he must adhere to his agreement. The arrangements surrounding the practice at B—— are not such as to induce us to alter our opinion.

M.D.—The matter is one upon which we see no very good reason to comment, for the patent preparation is not called by the medical man's name, and in the abridged description sent to us from the local paper the fact that the patentee is a medical man is not mentioned.

L.R.C.S. and P. (Pilsley) has omitted to say what appointment it is concerning which he is inquiring.

G. L. K.—The matter is not without difficulty. We will write.

The substance of *H.B.'s* letter has been forwarded.

METEOROLOGICAL READINGS.

An Inaugural Address

ON

CERTAIN UNDEFINED FACTORS IN THE SPREAD OF DISEASE.

Delivered before the Chelsea Clinical Society on Oct. 18th, 1898,

BY J. FOSTER PALMER, L.R.C.P. LOND., M.R.C.S. ENG.,

PRESIDENT OF THE SOCIETY.

GENTLEMEN,—I must first take this opportunity of thanking you for the honour you have done me in selecting me to be the first President of this society. A man can have no greater honour than to be thus chosen by those best qualified to judge of his shortcomings—viz., those of his own profession. I can only hope, with the help and support of the vice-presidents, committee, and secretary, that the said shortcomings will not be conspicuous during my year of office. Secondly, I must express an ardent and somewhat confident hope in the future of the society. May it be useful and permanent. A society, it is true, may be useful though temporary. But I am not sure that now local societies may not have before them as long and useful a career as central ones. Decentralisation is one of the marks of progress of the age. There is another factor which makes for the stability of this society. It is largely composed of general practitioners, and there can be no doubt to those who watch the signs of the times that the future of medicine is in the hands of the general practitioner. The physician, as such, must sooner or later become extinct. The pure general consulting physician is already almost a rarity. "Send for a specialist," is now the almost universal cry. It is only the antique type of patient who thinks of calling in a "physician." The very word is barbarous: faulty in its derivation and its root obsolete or degraded. We do not "physic" people now in the old sense. If a "physician" means anything it means a student of "physics," not of "physic," a slang word for drugs. We need a new word derived from the Latin "medicus," or, better still, the Greek κλινικός. The physician has done good work, from the time of Linacre, of Caius, and of Harvey, to the present, but his days are numbered. So great has been the progress of surgery during the last thirty years in comparison with that of medicine that we have now almost come to look upon the physician as the lame and halting follower of the surgeon. One by one, too, his provinces are invaded. The great abdominal cavity has practically gone over to the surgeon; the thorax and the nervous system are in the hands of the specialist; the investigations on fevers are largely carried on by the bacteriologist; while the treatment of diphtheria often falls to the throat specialist, who is generally a surgeon. There will be nothing left. If anything is left it will be swallowed up by the Roentgen rays, which will become another speciality, and will, I have no doubt, do much to bring medicine once more abreast of surgery. Long before the close of the coming century the profession will consist mainly of general practitioners and specialists, with a few operating surgeons. The bacteriologists will probably be outsiders. Meanwhile, it remains for us, individually as men and collectively as a society, independently of any shuffling of cards within the profession, to do our best to maintain the high tone and standard which has always, as a rule, characterised its relations with the world outside.

And, thirdly, I have to bring forward some subject of general interest, and, if possible, of usefulness also, to the members of the society. We are a *clinical* society. We have elected, and rightly so, to base our researches primarily on the visible manifestations of disease which we see before us at the present time and in the human subject. But we need not, and we must not, neglect as collateral branches the great records of the past, which show us the course of disease on a larger scale, or the experiments of the laboratory, which show it to us under changed surroundings. These, however, are secondary; our *primary* object is to know the effect of disease, not on other people in other times, nor when cultivated in bottles or on potatoes, but on the particular individual subject before us. For this purpose we must know something of the patient besides his disease. Each patient we see has a distinct pathological individuality; our prognosis of any single case depends more on our knowledge of the life, habits, surroundings, and hereditary tendencies of the patient than on the character of the disease itself. "I know," says the old doctor in one of Oliver Wendell Holmes's works,—"I know the families that have a way of living through everything, and I know the other set that have the trick of dying without any kind of reason for it. I know the folks that think they're dying as soon as they're sick, and the folks that never find out they're sick till they're dead." For this reason, valuable as are hospital records and observations for making out statistics of mortality and the study of morbid anatomy, there are matters of vital importance to a true study of medicine which can only be observed in private practice.

We are sometimes told that our only duty as students of medicine is to observe and collect facts and tabulate results; that we must have no ideas and formulate no hypotheses. I venture to say that this is absolute humbug. No man, woman, or child, ever yet took the trouble to collect facts unless he had some theory to verify. It is this that gives him his interest in the work. The idea may be wrong, it may be changed in the course of the investigation; but it has been worked out in the mind before the investigation commences. Do you suppose Harvey would have made his numerous experiments, Hunter have dissected his lions and tigers, Jenner have spent his time inoculating with vaccinia, or Lister tried his antiseptic treatment, if they had not already thought out some hypothesis which they hoped to prove, but might disprove? There is no dearth of facts. They are as plentiful as blackberries. There are tons of them. What we want is the intelligence to weigh, to interrogate, to classify, to examine and get at the relative value of them. "Non numerandæ sed perpendendæ sunt observationes." There may be men who are fit for nothing better than to collect facts for others to work upon. If so, let them do it. But lack of brain-power is not a common complaint in our profession; and if we have brain-power it is our duty to use it. We have, all of us, a valuable store of knowledge and experience, the outcome of daily observation, which we use for our own and our patients' benefit. It is almost criminal not to attempt to make some further use of it for the public good and for future generations. This society affords us one opportunity of doing so.

In discussing some of the uncertain factors in the spread of disease I must confine myself to three, the extent of whose influence is still doubtful and undefined. These are: (1) pathogenetic evolution; (2) retrograde metamorphosis; and (3) abnormal objective receptivity. Contagion and infection, in view of the researches of bacteriology, can no longer be considered doubtful causes and can only be discussed in their relation to the foregoing. Practically all diseases may be considered communicable. Inoculation, contagion, and infection merely imply different degrees and conditions of communicability. With the leprosy bacillus actually before our eyes we can no longer doubt the wisdom of the great Hebrew legislator in looking upon leprosy as a contagious disease and enforcing disinfection and quarantine by stringent laws. This is only one of numerous instances in which the opinions of the ancients, having been discarded and ridiculed for centuries, have been found to be true ones after all. What appears to be ignorance or superstition is often merely truth expressed in metaphorical language. When Herodotus tells us that Venus inflicted a loathsome disease on the Scythians for violating her temple we have not much difficulty in the diagnosis, although we with our supposed superior wisdom should express it differently. Perhaps, after all, the Greeks knew as much of the pathology of syphilis as we do. Whether they were acquainted with bacteria evidence does not show. At any rate, antiseptic treatment was not unknown to the Romans. It is alluded to by Virgil in the third book of the Georgics:—

> "Aut tonsum tristi contingunt corpus amurca,
> Et spumas miscent argenti, et sulfura viva,
> Idæasque pices, et pingues unguine ceras,
> Scillamque, elleborosque graves, nigrumque bitumen."
>
> Lib. iii., ll. 448–451.

We find mentioned in these four lines (besides squill and black hellebore) the bases of nearly all the antiseptics of the

Digitized by Google

present day, olive oil saturated with some substance not stated, nitrate of silver, sulphur (probably sulphurous acid), tar and paraffin, with lard and wax for ointments. These were used as protectives against disease. For what reason if not to prevent the ingress of bacteria?

During the plague of London in 1665 the bacterial origin of the disease was distinctly anticipated, and, as usual, ridiculed, as you may see on reference to Defoe's "Journal of the Plague."[1] The same has occurred much more recently. I have a copy of part of the evidence given before the Commission appointed to inquire into the sanitary state of the army in India in 1861. One of the experts examined, Surgeon-Major Wallich, a well-known microscopist, said he believed that the causes of malaria, fevers, dysentery, and cholera (which he defined as minute plants) might be made quite visible by the microscope. At this suggestion Sir Ranald Martin, one of the members of the Commission, walked out of the room, because, as he afterwards confessed to the witness, he thought the latter was talking "nonsense." The "nonsense" of forty years ago is thus the accepted science of to-day, while some of the discarded hypotheses of antiquity are found to contain a substantial basis of truth.

Let us not, therefore, discard everything that is old simply because it is old or grasp at everything that is new simply because it is new. There is very little real evidence to show that the human intellect is better now than it was in the time of Homer. Our morals are better (I hope), our tools are better, and we have more knowledge and experience in the use of them, but I am afraid this is all. We are naturally elated at our progress in the comparatively new field of bacteriology, but we must rejoice with trembling. Twenty years of further progress in this field will shed a far different light both on etiology and treatment from that we now see by. With regard to the latter, it is hardly possible that the study of therapeutics will ever resolve itself into a long list of immunised sera. It is more probable that the chemical products by means of which immunisation is brought about will be known and manufactured by artificial means, and that thus therapeutics will become an exact science instead of an empirical art. With regard to the former there is also much to be learnt, and the three factors referred to above—(1) pathogenetic evolution; (2) retrograde metamorphosis; and (3) abdominal objective receptivity—are only types of a large number of unknown or imperfectly known conditions under which the pathogenic bacteria increase and multiply, effect an entrance into the human body, and when there convert some of its natural organic products into deadly poisons. To keep ourselves constantly abreast of the latest researches in this department of science will be one of our most important objects.

I. *Pathogenetic evolution.*—The ancient belief in the possibility of spontaneous generation in the organic world has long ago died a natural death and has been followed by a belief that every organism is produced by one like itself in every particular, or at least by one of the same species. This view, however, has been shown by the researches of Charles Darwin to be true only in part. It is now generally admitted that generation is progressive and that the more complex organisms have been gradually evolved from simple ones. Even if evolution is not a complete solution of organic life, but is subject, as I believe it is, to exceptions and reversions, it is still a force to be reckoned with. It is therefore natural that when we come upon a comparatively new branch of biological study like that of bacteriology we should ask ourselves what part, if any, is played by evolution in the history and progress of disease. Have the microphytes of all the diseases flesh is heir to come down in an unbroken line of descent or are they traceable to some simple germ of prehistoric ages when man's only diseases were the wounds received in battle with those extinct monsters he has now exterminated? And what relation in the biological scale do these organisms bear to one another? Are those most destructive to life to be considered higher or lower in the scale than those which only cause inconvenience? Are plague and cholera, e.g., higher types than influenza, small-pox than chicken-pox? These questions must be answered before medicine is an exact science. It is of the utmost importance that we should know whether the micro-organism of influenza (if there is one) can ever become evolved into the organism of cholera or of plague; whether the microphyte of syphilis can under any special conditions, or after an innumerable succession of slight variations, evolve itself into that of leprosy or of cancer; whether any of the bacteria found in ordinary membranous or herpetic sore-throat may, with favourable surroundings, develop either in the same patient or during the course of an epidemic in other patients the well-known Klebs-Löffler bacillus of diphtheria.

1. It is among the records of past epidemics that we must first look for evidence of evolution in disease, for there only can we trace it over sufficiently long periods of time. The oldest known disease is plague. There is no doubt that plague has existed in the world more than 5000 years, and it is still endemic in Egypt and the adjacent parts of Asia and Europe. The earliest epidemic on record is one mentioned by Manetho, the Egyptian historian, as occurring in Egypt in 2500 B.C. From a very early period, in nearly all the ancient writers, there are accounts of constantly recurring epidemics bearing the same general features in the same geographical area. We find them in the Old Testament, in the "Iliad" of Homer, in Ovid's "Metamorphoses" (vii.), in Plutarch's Lives, in Thucydides, in Livy, in Strabo, in Tacitus, and in Pliny. When we come to the plague of Athens, described by Thucydides, and that of the sixth century, by Gibbon, there is no longer any doubt that we are dealing with the same disease that is still endemic in Turkey and in Egypt and was lately so prevalent in Hong-Kong. "The greater number," says Gibbon, "were surprised by a slight fever. The same, the next, or the succeeding day, it was declared by the swelling of the glands, particularly those of the groin, of the arm-pits, and under the ear, and when these buboes or tumours were opened they were found to contain a *coal* or black substance of the size of a lentil." Translate this into modern bacteriological language and we have almost an exact counterpart of the most recent descriptions of the same disease. "Plague," says Kolle in a paper on the plague bacillus in the *Deutsche Medicinische Wochenschrift* of March 4th, 1897—"plague is a polyadenitis, the glands being the starting-place of a septicæmia." "Black pustules or carbuncles," says Gibbon. "Carbuncles, pustules, spots, and petechiæ," says Aitken, almost word for word. Thus we appear to have been dealing with the same disease for two thousand, probably for four or five thousand years. If evolution were the law of pathological life we should expect, considering the short life-history and rapid generation of micro-organisms, to see some change of type in disease after so long a period. The history of the plague does not seem to favour this view. The only difference appears to be that it is less fatal than in the third, sixth, and fourteenth centuries, when it is said to have carried off one-fourth of the population of the world. This is clearly the result of improved sanitation.

Let us take another standpoint. If plague is always the same disease whenever we find it, is the general type of disease changing and is the plague gradually giving way to some other pathological manifestation? Since the seventeenth century it has been practically extinct in the British Isles, although for a thousand years it had been constantly epidemic if not endemic,[2] and during these last two centuries it has been steadily retiring from the continent and going back to its original haunts in Turkey and Egypt. It is possible that plague and cholera may have existed side by side, as they do now, from the foundation of the world; but it appears as if the position formerly held by the former had during the last hundred years begun to be occupied by the latter. We need not accept without question the statements of all the ancient writers, but we cannot deny their knowledge. The writer of the "Iliad," who must have lived 3000 years ago, was a better anatomist than his translator Pope, who lived in the last century. Homer never confused nerves with tendons as Pope did in the description of Achilles's operation on the dead body of Hector.[3] In Walford's "Chronology of Pestilences" there is a list of about 1700 epidemics beginning 2500 B.C. and ending with the plague in Persia and Alaska in 1882. Of these, the large

[1] "Which I look upon with contempt . . . . likewise the opinion of others who talk of infection being carried on by the Air only, by carrying with it vast numbers of Insects, and invisible creatures, who enter into the Body with the Breath, or even at the Pores with the air, and then generate or emit most accute (*sic*) Poisons or poisonous Ovæ (*sic*), or Eggs, which mingle themselves with the Blood, and so infect the Body."

[2] One of the first records of plague on an extensive scale in the British Isles was in 665 A.D., the last in 1665 or 1667 A.D., a plague-wave of just 1000 years. On the continent it began earlier and receded later.

[3] X, 395-404, Pope, xxii., 495-510.

Digitized by Google

majority (between 900 and 1000), 54·47 per cent., refer almost certainly to the plague, the rest being made up of epidemics of uncertain type, of dysentery, leprosy, throat affections, venereal disease, intermittent fevers, small-pox, and other epidemic fevers, and in the later centuries of influenza, typhus fever (including typhoid fever), and cholera. In the twenty-five centuries B.C. the proportion of plague to other diseases is 137 to 18, 88·38 per cent. In the first five centuries A.D. the proportion is 61 to 17, or 69·43 per cent.; in the five following centuries it is 99 to 37, or 72·79 per cent.; in the eleventh century 37 to 14, or 72·54 per cent.; in the twelfth century 28 to 10, or 73·15 per cent.; in the thirteenth century 46 to 8, or 85·18 per cent.; in the fourteenth century (including, of course, the Black Death, which devastated so large a portion of the world and besides which all other epidemics sink into insignificance) 55 to 57, or 49·1 per cent.; in the fifteenth century 82 to 31, or 72·56 per cent.; in the sixteenth century 127 to 63, or 66·84 per cent.; in the seventeenth century (which includes the Great Plague of London) 144 to 96, or 60 per cent.; in the eighteenth century (including the plague of

plague and the advent of cholera, where it is 50 to 245, or 16·94 per cent. (Table IV.). These figures, again, are hostile to any belief in a continuous line of pathogenetic evolution, although cholera seems to have stepped into the place formerly occupied by plague. But evolution may take another form. If the general type of disease does not change from century to century is it possible that a series

of shorter changes takes place and that the milder epidemics may evolve, in the course of a few months or years, under favouring conditions, into the more fatal ones? It has been constantly observed, both in ancient and modern times, that the great destructive plagues have been preceded by minor epidemics of catarrh, influenza, measles, and diseases of a less virulent type. Thucydides, a careful observer, says that during the plague of Athens other diseases declined. "None of those diseases to which they were accustomed afflicted them at this time, or whatever there was ended in this" (Hist., lib. ii., 51). More recent observations confirm this. The fatal Black Death of the fourteenth century was preceded by a long succession of outbreaks of influenza and other less fatal epidemics.[4] Of the nineteen epidemics recorded by Dr. Theophilus Thompson in the "Annals of Influenza" seventeen at least were followed by epidemics of a more fatal character: those of 1510, 1557, and 1580 by plague; that of 1658 by a series of continued fevers until 1664; then by malignant fever (probably typhus fever), and this by the Great Plague of 1665; that of 1675 by small-pox and dysentery; that of 1710 by plague; that of 1729 by typhus fever, small-pox, and cholera; that of 1738 by diphtheria; that of 1743 by typhus fever; that of 1758 by scarlet fever; that of 1762 by dysentery; that of 1775 by scarlet fever and diphtheria; that of 1803 by typhus fever; those of 1829, 1831, 1833, and 1837 by Asiatic cholera; also that of 1847 (Table V.). That of 1829 is very remarkable; for cholera,

having travelled from India to the south of Russia in 1823, patiently waited seven years for the influenza epidemic, and then immediately spread through the whole of Europe, following practically the same route. Coming to more recent times, the epidemic of influenza in Iceland in 1862 was followed by an extremely virulent epidemic of pneumonia the following year. These facts are striking if evolution could be otherwise established, but alone they only point to a bare possibility.

2. Then arises the question, Does evolution ever take place in the progress of a single case? This clinical observation must teach us, and it is one which may well be borne in mind by those who place their experience at the disposal of this society. My own experience leads me to conclude that it is certainly not the rule and that the exceptions may be explained in other ways. The very rarity of the occurrence makes each instance of it a subject of special observation. When we have once made up our minds that a certain doubtful case of sore-throat is not one of diphtheria we are

[4] The first recorded general epidemic of influenza was in 1173. Besides numerous instances recorded in history of plague being preceded by epidemics among the lower animals it is found that in the present day, whether in Asia or Africa, it is usually preceded by an enormous mortality among the rats.

Digitized by Google

not much disturbed by the thought that it may develop into diphtheria later. It is possible, of course, that the diphtheria bacillus may be engrafted on a sore-throat of some other description, but this seems to be rather unusual. The same remarks apply to doubtful cases of scarlet fever, small-pox, typhus fever, and typhoid fever. Some years ago I saw a case of soft chancre under the prepuce which had been neglected for two years. Amputation became necessary and microscopic examination amply confirmed the diagnosis that the case had now become one of epithelial cancer. The patient died shortly after from a recurrence of the disease. Sir James Paget, who must have had more experience of cancerous tumours than most men, had never seen a case before. The chancre, by reason of its chronicity, had become a suitable soil for the cultivation and growth of the cancer microphyte. The rarity of such cases makes it highly improbable that they are due to any general pathological sequence.

There is, however, another class of cases in which we might be led to expect from the frequency of their occurrence a more natural order of transition from one disease to another. We have spoken of influenza being followed by other epidemic diseases in the same geographical area, but pneumonia following a specific attack of influenza in the same patient we are all familiar with. The zymotic nature of pneumonia is now generally admitted[6] and its micro-organism is known. The influenza epidemics of 1891 and 1892 were especially fatal on account of pneumonic complications. Clinical observation here seems to indicate a special and direct tendency for one zymotic or epidemic disease to run into another of a more virulent type. Whether or not this is an instance of micro-organic evolution can only be finally decided by observation in the bacteriological laboratory. On the other hand, has not clinical observation constantly shown us that in the greater epidemics, whether of plague or cholera, a steady diminution of intensity is the rule? From a mortality of 90 per cent. at the onset of the epidemic it gradually falls to 10 per cent. or less. Is not this an upside-down kind of evolution—degradation rather than progress? In the case of specific attacks of zymotic disease, too, the tendency is, with the exception noted above, to run on to what we consider to be lower forms. We may be wrong in our estimate of the relative biological importance of diseases or of the correct position in the social scale of the various bacteria, but we naturally look upon scarlet fever as a higher type of disease than its sequelæ, nephritis, otitis, stomatitis, rheumatism, &c.; typhus fever and typhoid fever than pneumonia; measles than bronchitis; small-pox than ophthalmia or purulent absorption. Thus, whether we consider the variations of epidemic disease from century to century, or those of a single great epidemic from week to week or from month to month, or those which occur in the course of an attack of zymotic disease in the individual patient from day to day, retrogression appears to be the rule, and evolution, contrary to the general order of organic nature, the exception.

3. We have now to inquire what bacteriology has to say on the subject. At the threshold of this inquiry we are met by the very important experiments of Pasteur on the somewhat similar organisms of mould and yeast. After a long series of experiments and counter-experiments by various observers it has been conclusively demonstrated that it is not possible by any methods of selection or changes of environment through any number of generations to cause mould to evolve into yeast or yeast into mould. These experiments, however, although useful as a standpoint, are by no means conclusive on the general question. If I understand evolution at all it would be equally impossible, however many millions of years were allowed for the experiment, to turn man into an ape or the ape into a man. Yet this would be no proof that they had not the same ancestor. Nor should we with any greater facility breed a horse from a donkey or *vice versâ*. Yet no one now doubts that the horse and the ass are both descended from the extinct hipparion. That there exists under certain conditions a tendency, limited perhaps in extent, to some evolutionary process seems to be shown by the experiments which have been made on the typhoid (Eberth-Gaffky) bacillus and others. These bacilli—the typhoid bacillus, the bacillus enteritidis of Gärtner, and to a still greater extent the bacillus coli communis—are found to increase in virulence in passing through the bodies of animals. In the last-named, according to Dr. Sidney Martin's experiments (referred to in the Croonian Lecture at the Royal College of Physicians of London), evolution seems to proceed in a regular mathematical series, the same effects being produced at first by 6 c.c. of a certain culture then by 4 c.c., then by 2 c.c. (then by 1 c.c.?), then by 0·5 c.c., then by 0·25 c.c., and then by 0·1 c.c. Many observers, too, he says, have noticed not only an increase in the numbers, but also an exaltation of this bacillus in the course of a case of typhoid fever. The experiments of Marmorek on the streptococcus pyogenes point to precisely the same conclusion. The pathological powers of this organism were greatly exalted "by alternately growing it in guinea-pigs and in a medium made of human blood-serum and bouillon."[6] The virulence of the typhoid bacillus was augmented in like manner, but less rapidly than the bacillus coli. Beginning with 4 c.c., the same effect was produced at the thirteenth inoculation with $\frac{1}{2}$ c.c. and at the sixteenth with half a platinum loopful (whatever quantity that may represent) of an agar culture. None of the ordinary laboratory cultures of the typhoid bacillus, Dr. Martin found, would kill an animal until they had been rendered virulent; in other words, until they had undergone the process of evolution in the bodies of certain animals and under certain special conditions.

There is, therefore, no doubt that, independently of any increase of the number of bacilli in the serum, the later generations of these organisms have a greater functional activity than the earlier ones; and functional activity is in organic nature generally the prelude to structural development. "It is manifest," says Mr. Herbert Spencer, "that there can be no variation of structure but what is directly or indirectly consequent on variation of function." "Function is from beginning to end the determining cause of structure."[8] At the same time they seem to exhibit a very strong tendency towards reversion to the earlier types. This, I think, is as far as the results of bacterial research will at present carry us. Whether microphytic life goes on thus throughout the ages in a series of advancing and receding cycles of short duration, or whether it has an earlier and a later history, one preceding its least virulent and one succeeding its most virulent stage must be left to occupy the minds of future observers. At present, observation has not extended beyond these two points. There are two distinct lines along which this extended life might proceed. In the first place, the micro-organism might commence its existence in a low form of pathogenic life as the organism of some mild catarrhal or local affection and evolve into that of one of the greater epidemics. And secondly, it might begin its career as one of the harmless or useful bacteria acquiring pathogenic functions at a certain period of its career, and losing them again as it passes on to higher forms of life. Major Giles, I.M.S.,[9] in a paper on the Micro-organisms of Pneumonia, goes so far as to say that "the difference between the organisms of disease and those found everywhere in earth and water are so small that it must be conceded that they cannot have diverged far from some common parent stem." The evolutionary theory certainly receives some support from the numerous instances in which the greater epidemics have been preceded by epidemics of a milder character as well as in many cases by epidemics among the lower animals. At the same time it seems to be negatived by the remarkable permanence of type which is found to have extended over thousands of years as well as by the extreme rarity of any change of type in the history of individual cases. The particular instance of the organism of influenza developing into that of pneumonia is hardly conceivable in view of bacterial research, for the organisms belong to different species. That of influenza, which, however, has not yet been identified with any degree of certainty, is a bacillus while that of pneumonia is a coccus. This is a gulf we shall hardly be prepared to bridge over; certainly not within the limits of a single case. When we remember, too, that the symptoms of influenza have not yet been definitely induced by cultures of the bacillus and that these symptoms have actually been induced experimentally by inorganic gases[10] it seems at least possible that influenza

[5] In a recent trial one witness spoke of an attack of pneumonia being useful in "setting up the constitution." This is probably only a popular and somewhat unscientific way of expressing the fact of its protective influence against a second attack.

may not necessarily be in every case of bacterial origin, but may sometimes be the result of chemical products generated by other means. If this is the case it would perhaps explain the constant reference both in ancient and modern times to earthquakes and volcanic eruptions and the presence in the air of gases popularly called "mephitic vapours" as preceding pestilential outbreaks. There is no doubt that influenza does precede many of the greater epidemics, but this is no proof that the pathogenic microbes are continuous. An attack of influenza, whether of bacterial origin or not, would, by its depressing influence on the nervous system, render the subject of it less resistant to the attacks of zymotic disease. Thus the direct causes of influenza would be the indirect causes of the epidemic which follows it. To this category, as we have already seen, pneumonia undoubtedly belongs. We are forced, therefore, to the conclusion that the causes of pneumonia following attacks of influenza are to be looked for in the increased receptivity following the latter disease rather than in any direct succession of micro-organisms, and that however tempting and plausible may seem the hypothesis of pathogenetic evolution it is not, in the present state of our knowledge, supported by any trustworthy proof.

II. *Retrograde metamorphosis.*—When we come to the subject of the decomposition of animal and vegetable matter as furnishing a nidus for the growth and development of pathogenic organisms we are on surer ground. Its influence on the spread of disease, indeed, has in recent times been strenuously denied and so has the protective influence of vaccination. Such "argumenta ad ignorantiam" may be good enough for politicians, hardly for scientific men. In this instance past history, clinical observation, and bacterial research all agree in affirming some relation of cause and effect between the presence of decomposing organic material in air and water and the prevalence of zymotic disease.

1. All nations and races, whether savage or civilised, ancient or modern, have made careful provision for the disposal of the dead. This is a universal recognition of the evil effects following the exposure of decomposing organic matter. The onset of epidemics, too, from time immemorial has always been referred to the period of autumn, when the ground is covered with fallen leaves and decaying vegetation. We may go back to Homer. We find in the twenty-second book of the "Iliad":—

> Ὃν τε κύν' Ὠρίωνος ἐπίκλησιν καλέουσι·
> Λαμπρότατος μὲν ὅδ' ἐστὶ, κακὸν δέ τε σῆμα τέτυκται,
> Καί τε φέρει πολλὸν πυρετὸν δειλοῖσι βροτοῖσιν.
>
> X. 29, 30, 31.[11]

Everything goes to show that Homer was an accurate observer. Virgil also. In the third book of the Georgics we have the same fact expressed:—

> "Hic quondam morbo cœli miseranda coorta est
> Tempestas, totoque autumni incanduit æstu,
> Et genus omne necî pecudum dedit, omne ferarum;
> Corrupit lacus; infecit pabula tabo."
>
> III., ll. 478–481.[12]

It is again repeated by another great observer, Shakespeare, in his "Henry V.":—

> "A many of our bodies shall no doubt
> Find native graves; upon the which, I trust,
> Shall witness live in brass of this day's work:
> And those that leave their valiant bones in France,
> Dying like men, though buried in your dunghills,
> They shall be fam'd; for there the sun shall greet them,
> And draw their honours reeking up to heaven;
> Leaving their earthly parts to choke your clime,
> The smell whereof shall breed a plague in France."
>
> Act iv., sc. 3.

The consensus of opinion is striking. Indeed, all observation, ancient and modern, tends to show that this view is well founded. The greater epidemics since the world began have always shown a decided preference for the autumn and late summer or else they have followed close upon large battles and extensive military campaigns, when the air has been impregnated with the emanations from the dead bodies of slaughtered human beings and animals of war, or after epidemics among the lower animals, vertebrate or invertebrate. The decomposing material may proceed from dead horses or cattle, rats or locusts. Koch found that a large mortality among the rats was always looked upon as a certain precursor of the plague, whether in Africa, India, or China.

The Great Plague of London commenced in November, 1664, and after remaining quiescent throughout the winter reached its maximum degree of virulence the following autumn. More than half the entire number of fatal cases took place during September and the first two weeks in October. The same sequence of events took place at the plague of Moscow. It was first introduced in November, 1770, remained inactive during the winter, and reached its climax in September, 1771, the mortality at one time being 1000 a day. The great cholera epidemic in this country ran a similar course. It began to take on an epidemic character in October and November, 1848; declined, but was not extinct, during the winter, and reached its highest rate of mortality the first week in September, 1849, during which 2000 deaths occurred in London. In the first cholera epidemic, too, that of 1832, by far the greatest number of deaths took place in September. Towards winter, when the temperature is lower and decomposition less active, epidemics almost invariably decline. The more recent epidemics of influenza, even, have been most active in the milder winters, being apparently postponed for a time when the weather is particularly severe. A low temperature means a partial arrest of decomposition. It would seem, therefore, that whatever may be the organisms by means of which disease is conveyed the condition of the atmosphere most favourable to their development and transmission is that resulting from the presence therein of those proximate constituents of organic life which are formed during the retrograde metamorphosis of animal and vegetable tissue. Under no other conditions does this process take place upon so extensive a scale as on the field of battle. Epidemic disease, both among human beings and animals, has always followed in the wake of war. It is not that pestilence is a necessary sequence, but that favourable conditions are brought about for the spread of any epidemic which may be latent. When from the carnage of battle or from any other cause the atmosphere has been impregnated with decomposing animal matter it forms a suitable nidus for the cultivation and development of any pathogenic organisms which may chance to be introduced into it. This took place in this country during the wars between Charles I. and the Parliament in the seventeenth century, and when, a few years later, in 1665, the plague was introduced it raged with excessive violence. The plague of Copenhagen, too, in 1712, followed the invasion of Denmark by Charles XII. of Sweden. And in those regions where certain zymotic diseases are always endemic or latent—i.e., in the vicinity of their natural geographical distribution—war is almost invariably followed by an immediate outbreak. In addition to the accounts given in ancient history, which are too numerous to mention, we find that in the present century every attack of Russia upon Turkish territory, which may be considered the natural home of the plague, has been followed by an epidemic of the disease. The Crimean War was no exception. Nor was the Russo-Turkish War of 1877-78. On the latter occasion plague broke out at Astrakan in the Caucasus and at several places on the Volga; and it was thought by many that we were then within measurable distance of a European outbreak. In this country no prolonged military operations have taken place since the latter part of the seventeenth century. Since the reign of James II. there has been no civil war except the short-lived rebellions of 1715 and 1745. The cessation of civil war was exactly coincident with that of the plague.

2. It is hardly necessary to appeal to modern clinical experience to confirm this great consensus of opinion. The dangers of overcrowding are practically recognised by all. And overcrowding is, after all, simply the presence in the atmosphere of an increased proportion of the decomposing products of animal exhalations, forming a nidus for the propagation of pathogenic bacteria. If the modern open-air treatment of phthisis has any meaning at all it means that even the tubercle bacillus, except in advanced cases of phthisis, is powerless for evil if it be not sufficiently supplied

form the air with the products of retrograde metamorphosis to form a suitable soil for its cultivation. The dangers of the post-mortem room can only be accounted for in the same manner. Decomposing organic tissue is inhaled by the lungs and any microbes introduced through a wound in the skin may find in the blood the necessary nidus for their growth. This condition of susceptibility may be transferred, as is well known, to a puerperal or surgical patient either through the exhalations of the lungs or from contact with the skin. The explanation in all these cases is the same. I have known one member of our profession who, without the least abrasion of the skin, was always attacked with erysipelas after being present at a necropsy, whatever might have been the cause of death. The entrance of decomposing material into the lung was sufficient to excite bacterial growth.

3. The experiments of the laboratory appear in this case fully to bear out the conclusions both of ancient history and of modern clinical experience. The fact stated by Dr. Arthur Ransome[13] that tubercle bacilli are killed by daylight and fresh air means, in other words, that they are unable to grow without the presence of decomposing organic tissue in the atmosphere. His most successful cultivations were made on the condensed moisture of the breath both of healthy and phthisical people, of the air of a wine-cellar, of that of a weaving-shed in Blackburn, and of that in the cellars of some insanitary cottages. Indeed, experiments have abundantly shown, and practically all observers will agree, that none of these organisms will submit to cultivation except in the presence of organic matter, and if such matter is found at all in the atmosphere it is in the form of certain products of retrograde metamorphosis. In the absence of these products the growth of bacteria, and consequently the spread of disease, must be practically *nil*.

III. *Objective receptivity.*—The first question that meets us here is whether receptivity is a normal or an abnormal condition. Is the human body the natural habitat of the pathogenic organisms or is it only certain exceptional individuals, certain exceptional morbid conditions, which furnish the necessary pabula for these microphytes to grow and thrive upon? "To breed vegetation," says Dr. Giles in a paper already referred to, "accustomed to develop in the blood of a living mammal, on scraps of potato, on gelatin, and what not, seems at first sight much like attempting fish culture out of water." The fact thus stated suggests the possibility that such organisms may not, after all, have any special affinity for the animal tissues, but may have commenced their career on other soil. In other words, is it the animal tissue *per se* or is it the animal tissue plus some pathological disturbance which forms a nidus for the reception of the pathogenic organism?

1. We shall not be able to answer this question by an appeal to the history of past epidemics. At the same time there are certain broad facts we are taught by a reference to such history, the knowledge of which will clear the ground for further inquiry. In the first place, we find that the pathogenic state is distinctly exceptional. Only once or twice in the history of the world has epidemic disease even appeared to threaten a universal prevalence. We find, too, in the constant association of famine with pestilence an indication that the pathological effects of starvation are in many cases the determining causes of the extensive incidence of epidemics. A similar pathological condition, but originating in the nerve-centres instead of in the blood, is brought about by licentiousness, while the auto-intoxication caused by sloth and gluttony has been found by experiment to be an equally potent factor in the incidence of zymotic disease. Both these factors have been at work in most pestilential periods. The earlier part of the fourteenth century preceding the Black Death was a time of unbridled luxury and debauchery. A reference to the "Decameron" of Boccaccio will convince anyone of this. He himself attributes the enormous mortality in Florence chiefly to this cause. It may also explain the greater susceptibility of Eastern nations generally than Europeans to plague and to cholera. The converse certainly explains the extraordinary longevity and healthfulness of the Jews both as a race and as individuals.

Coming to more recent records, the remarkable fact already mentioned that most of the greater epidemics of the last five centuries have been preceded by influenza, a disease the origin of which we have not yet been able to trace, again points to the conclusion that some preliminary cultivation is necessary before the human subject falls a victim to the onslaughts of pathogenic bacteria. The comparative infrequency with which these organisms run their virulent, and what we suppose to be their natural, course in the animal body is not in itself a proof that the latter is foreign soil. Waste, as we should call it, appears to be a part of nature's system. There are probably thousands of seeds, animal and vegetable, wasted to every one that grows. Still, it is consistent with its being so, and the frequency of this initial preparedness when they do run that virulent course is *primâ-facie* evidence that it is.

2. Nor is the evidence of clinical observation by any means conclusive. Few would venture to say offhand whether, *ceteris paribus*, zymotic disease attacks by preference the healthy or the unhealthy. Naturally most men would take the latter view, and they would be justified in doing so; but the apparent exceptions are so numerous that we are often staggered in our opinion. This, I believe, is partly due to an ancient superstition, not yet extinct even in our profession, which associates health with a florid complexion and a tendency to obesity. As a matter of fact the contrary is more often the case. Granted that in our present state of civilisation no man's sanitary condition is perfect, the pale, thin student, the active brain-worker and consumer of midnight oil, is a nearer approach to the perfectly healthy type than the red-faced, muscular, fox-hunting squire or the equally muscular agricultural labourer. On this subject I quote the words of a great observer of human nature, the High Master of St. Paul's School; he says: "I do not hesitate to say that if two boys start life together equally sound in constitution, and circumstances lead one to choose an open-air career of muscular exertion and the other the life of the study and the cultivation of the brain the student has the better chance of health and long life." Within the profession I have never yet heard this well-known fact so clearly stated. It is important to recognise it, for not until we can truly estimate the degrees of initial proximity to a normal standard, as well as the deviations caused by evil habits, modes of living, and hereditary tendency, can we even approach the question of receptivity from the clinical side. Meanwhile we are in possession of certain definite facts. We know the prevalence of epidemic disease after the depressing effects of influenza. We know—for we have excluded the possibility of pathogenetic evolution—that pneumonia constantly attacks those whose system is abnormally depressed by the effects of influenza, measles, &c., and even in many cases those whose normal habits of life are interfered with by enforced inactivity from accident. We know, too, that unless inoculated under the skin the syphilitic organism (as well as that of gonorrhœa) practically never invades the human system except when it is under the influence of the depression following an explosion of nervous force.

Heredity is another important factor in determining the incidence of disease. The susceptibility of some families to attacks of zymotic disease is truly striking. Such hereditary tendencies must have had an abnormal origin somewhere. In many cases it is not far to seek. I once knew a family the members of which appeared to catch small-pox on every possible opportunity independent of vaccination. Some were attacked twice, others three times, at intervals of five or six years. The father was a feeble, miserable-looking epileptic. Observation on a more extended scale shows that the children of drunken parents are more liable to attacks from prevailing epidemics and sink under them sooner than other people.[14] The above are both instances of known hereditary deviations from the normal standard. In other cases the tendency is seen, but its origin is lost in obscurity. We know, though we cannot account for, the remarkable elective affinity which seems to obtain between the typhoid and Klebs-Löffler bacilli and the members of our own Royal family. When any of these cases of illness have occurred numbers of other people without this special affinity have been subject to similar conditions, have lived under the same roof, breathed the same air, drunk the same water, eaten the same oysters, and, of course, have swallowed the same bacilli with impunity. In the *Practitioner* for August, 1898, Dr. Hector Cameron brings forward some striking instances of family tendency to diphtheria. In one case it was called "the disease of the family." In another, out of 23 descendants of one man 11 had diphtheria and 7 died.

[13] Experiments on Tubercle Bacilli (reported to the Royal Society) Brit. Med. Jour., April 23rd, 1898.

In nearly all the cases there was no communication between the different families. Lastly, we have the well-established fact of the concurrence of zymotic diseases. This is not a matter of popular observation only, but has been worked out statistically by Dr. Barnes of Eye, in Suffolk,[15] not in large towns, where the constant presence of zymotic disease would confuse the results, but in a number of small country villages with populations of under 10,000 and where zymotic disease is only an occasional visitant. (Tables VI. and VII.) It is inconceivable that the microbes

of measles and diphtheria, for instance, should elect to travel about the country hand in hand to the extent of 50 per cent. in excess of their estimated probable concurrence. We are thus driven to the conclusion that the microbes of both diseases are constantly present in the air and that some insanitary condition renders each individual liable to fall a victim to the first microbe that crosses his path; in fact, that personal receptivity is the determining cause of the prevalence of both diseases.

3. There are many of the recent researches in bacteriology which have an important bearing on this question. Among the most striking are those of Poehl of Vienna.[16] He finds that tissue respiration is always abnormal in infectious disease and that infection is always preceded by auto-intoxication. The causes he gives are—(1) diminished alkalinity of blood; (2) insufficient supply of oxygen; (3) abnormal fermentation processes in intestine; (4) poisoning from without; and (5) retention of metabolic products. These experiments, if confirmed, seem to be almost conclusive. Remlinger, of the Pasteur Institute,[17] fed eight rabbits for ten days on cabbage soaked in water containing cultures of the typhoid (Eberth-Gaffky) bacillus. The bacilli were found in the fæces all the time, yet only three of the rabbits took typhoid fever. It is possible, then—and this I want to draw special attention to—for an animal to have typhoid bacilli constantly passing through the intestinal canal without contracting the disease. This, I maintain, is what continually takes place under perfectly normal conditions. Of a similar character and tendency are the experiments of Dr. Friedländer and Major Giles, I.M.S., on pneumonia.[18] The latter failed to inoculate some recently captured dogs, while the former succeeded with others which had been confined. On the other hand, Dr. Friedländer failed with his newly-caught rabbits, while Major Giles successfully inoculated some that had lived in the insanitary atmosphere of a rabbit-hutch. I must confess that I am not yet entirely converted to a belief in the bacterial origin of rickets. Yet the remarks of Mercoli[19] of Italy on his experiments accurately express what I believe to be the case with regard to other pathogenic organisms. Rickets he believes to be caused by streptococci and staphylococci. These, he says, are constantly found in children's mouths and are as constantly being swallowed. As long, however, as the alimentary canal is healthy nothing happens, but if it is out of order they enter the blood and affect the nervous system and epiphyseal ends of the bones, causing a form of chronic osteo-myelitis. Dr. Arthur Ransome,[20] in his experiments on tubercle bacilli, found that they were killed by daylight and fresh air, two normal conditions which ought to be everywhere present for this purpose. In their experiments on the typhoid bacillus Achard and Bensaude "have shown that the agglutinating substance may be absorbed by all mucous cavities when introduced into them, provided that such introduction produces lesions. If, however, the mucosa remains healthy it is not absorbed."[21] This statement is made as bearing on an extremely rare case reported by Castaigne in *Médecine Moderne* for Nov. 13th, 1897, of the agglutinating property of the serum being communicated to a child four and a half years old from the mother's milk. In this case, which appears to be almost unique, the child was previously suffering from non-typhoid gastro-enteric disorder, which accounted for the transmission.

In dead or decomposing organic matter the pathogenic bacteria can, as we know, be cultivated *ad libitum*. In a perfectly healthy living body, free from lesions, free from auto-intoxication, and with all the secretions in their normal state (*inter alia*, the saliva itself is a powerful bactericide),[22] I doubt if they would ever be able to reproduce themselves in a virulent form. In other words, we may conclude that the pathogenic microbe is powerless to cause disease in an ideally healthy subject; it requires for its development a soil prepared for its reception, and such a soil does not exist in any perfectly healthy organ or organism. A healthy organism is one in which the brain is in a constant state of normal activity. There may be external conditions of air, water, and surroundings which render such a condition impossible, but in most cases the onset of zymotic disease is the sequel to some individual defect, either hereditary or acquired;[23] some cause of depression of the vital powers, either temporary or permanent.[24] The ancient writers were, perhaps, not altogether wrong when they attributed disease, metaphorically, to the influence of some evil demon. It

[23] The remarkable health and longevity of those who practically spend their lives in foul and unhealthy sewers shows how little the freedom from zymotic disease is necessarily dependent on such external surroundings.

[24] It is possible that here we may have to make an exception in favour of small-pox. The incidence of small-pox prior to vaccination and among the unvaccinated has been found to be so universal that this disease appears to have acquired an affinity for the human subject which has become a part of its nature. The recent Act of Parliament for the propagation of small-pox will soon give us the opportunity of renewing our experience of this disease.

would not be wrong to do so now. Of all such demons the most potent for evil is perhaps the demon of Sloth. It is Sloth which leads to ignorance and the neglect of all sanitary precautions. Individually, Sloth is the direct cause of auto-intoxication and the indirect cause of licentiousness and intemperance—all potent factors of susceptibility to disease. To this particular demon we are not, as a profession, especially liable, and we may congratulate ourselves that it is so. Indeed, we have some of us wished on occasion that we had rather more of it. But let us remember that idleness is not only an evil condition, but that it is an unhappy one. In the words of the great poet of the last century:

> "She mark'd thee there,
> Stretch'd on the rack of a too easy chair;
> And heard thy everlasting yawn confess
> The pains and penalties of idleness."[25]

If there is any danger of our ever lapsing into this state I hope it will be avoided by the mental work and food for thought which may hereafter be provided by the discussions and researches of the Chelsea Clinical Society.

FURTHER OBSERVATIONS ON A CASE OF TOTAL EXTIRPATION OF THE STOMACH IN THE HUMAN SUBJECT.

BY DR. CARL SCHLATTER,
PRIVAT-DOCENT AND ASSISTANT SURGEON IN THE SURGICAL KLINIK, ZÜRICH.

(*Specially translated for* THE LANCET.)

ON Sept. 6th, 1897, I performed total extirpation of the stomach in the case of a woman, fifty-six years of age, suffering from diffuse carcinoma of the entire stomach. The continuity of the digestive tract was maintained by stitching a loop of the small intestine to the lower end of the œsophagus and in the results the operation was a complete success. An examination made by Professor Ribbert showed that the excised stomach was affected with small-celled alveolar glandular carcinoma (Kleinalveoläres Drüsenzellencarcinom) and that of the two incisions isolating its extremities one passed through the œsophagus and the other through the duodenum. The patient recovered completely and on Oct. 30th I was able to show her at the meeting of the Central Association of Swiss Medical Practitioners held at Olten. My published articles on this case of œsophago-enterostomy, together with observations on nutrition and digestion after complete removal of the stomach, appeared in the *Correspondenz-Blatt für Schweizerärzte* (1897, No. 23), in the *Beiträge zur Klinischen Chirurgie* (vol. xix., Part 3), in the *Medical Record* (New York, Dec. 25th, 1897), and in THE LANCET (Jan. 15th, 1898). On April 14th, 1898, Professor Krönlein exhibited the excised stomach at the German Surgical Congress held in Berlin, gave a short account of the subsequent condition of the patient, and drew particular attention to the fact that this case was the only one which could with absolute accuracy be described as extirpation of the stomach, on which account it was of entirely exceptional value for the study of the digestive processes which take place in the absence of the stomach.

There are several reasons which induce me at the present time, fully nine months after the operation, to draw up a comprehensive account of the further progress of the patient and of the investigations which have hitherto been made upon her. A period of observation extending over nine months would in itself justify an elaborate report. She was fit for discharge long ago, but we have been permitted to retain her in the hospital, where she is well taken care of and has suitable occupation. On the one hand, we attached great importance to the protracted careful examination of the case and to the prolongation of the chemico-physiological observations, while, on the other hand, the very straitened circumstances of a friendless woman, now fifty-seven years of age, gave reason for apprehension that at her own home she would hardly have the food she required, to say nothing of proper cooking. Unfortunately, the hospital regulations with respect to admission will make her early discharge inevitable, which is an additional motive for the drawing up of a clinical report. Moreover, some important series of observations have been completed.

[25] The Dunciad.

On Oct. 30th, 1897, hardly eight weeks after the operative intervention, the patient had so far recovered from her cachectic state that the long railway journey and the appearance in public at Olten were in no way injurious to her. Her weight had increased about 4·4 kilos. (9½ lb.) since the operation. Her condition at that time may be best judged of from a dietetic error which was committed with impunity before she appeared at the meeting, for she took advantage of her first liberation from hospital control to indulge heartily in vegetables (cauliflower). A few weeks later, at the end of November, her food differed little from the ordinary patients' diet, and her hours for taking it have since then been the regular mealtimes of the other inmates of the hospital. The few departures which have been made from the ordinary patients' diet have been occasioned principally by her completely toothless condition. For some months she has been wearing artificial teeth, but her power of mastication is nevertheless far from being good. She felt herself at that time perfectly well and was engaged all day long at work of various kinds in the wards.

The following diet lists, selected from those of different months in 1898, will give a good idea of the quantity and kind of food which she took in the course of the day. [The grammes and cubic centimetres of Dr. Schlatter's MSS. are here represented by their equivalents in ounces.] Jan. 17th: Milk, 33 fl. oz.; coffee without milk, 13 fl. oz.; 3 rolls; 3 eggs; soup, 3½ fl. oz.; fried sausage, 4 oz.; stewed apples, 7 oz.; whortleberries, 3 oz.; and claret, 7 fl. oz. Feb. 5th: Milk, 11½ fl. oz.; 3 rolls; 3 eggs; soup, 4 fl. oz.; sweetbreads, 10½ oz.; cauliflower, 7 oz.; and claret, 7 fl. oz. March 4th: Milk, 10½ fl. oz.; coffee without milk, 7 fl. oz.; soup, 4 fl. oz.; roast veal, 4 oz.; carrots, 14 oz.; 4 rolls; and claret, 7 fl. oz.

Her hours for meals and the amount taken on each occasion were usually as follows:—6.30 A.M.: coffee with milk, from 7 fl. oz. to 10½ fl. oz., and 1 roll. 9.30 A.M.: 1 egg, 1 roll, and 3½ fl. oz. of claret. 12 noon: soup; half the day's allowance of meat and vegetables or fruit. 3 P.M.: coffee with milk, from 7 fl. oz. to 10½ fl. oz., and 1 roll. 6 P.M.: the remaining half of the day's allowance of meat and vegetables. 5.30 P.M.: 1 roll and 7 fl. oz. of claret Her animal food generally varied between roast veal, Vienna steak, chops or cutlets, beefsteak, fried sausage, brain, sweetbread, and fowl. Along with it there was given either something made with flour, groats, or eggs, or, in the absence of this, peas, beans, carrots, potato soup, cauliflower, stewed apples, whortleberries, small plums, and such like.

The following table of the patient's weight at different periods will be the best proof of the excellent assimilation of her food. When she was shown at Olten on Oct. 30th, 1897, she weighed exactly 36 kilos. (79¼ lb.), having gained about 4 kilos. (8¾ lb.) since the operation.

Date.	Weight. Kilos.	lb.	Date.	Weight. Kilos.	lb.
1897.			1898.		
Nov. 19th ...	36·5 =	80¼	Feb. 23rd ...	37·9 =	83½
Dec. 3rd ...	37·5 =	82½	March 10th ...	38·1 =	83¾
,, 17th ...	37·0 =	81½	,, 24th ...	38·1 =	83¾
,, 31st... ...	36·5 =	80¼	April 7th ...	39·0 =	85¾
1898.			,, 22nd ...	39·3 =	86½
Jan. 12th ...	36·5 =	80¼	May 10th ...	40·0 =	88
,, 25th ...	37·0 =	81½	,, 24th ...	38·2 =	84
Feb. 9th... ...	37·5 =	82½	,, 28th ...	39·0 =	85¾

Her greatest gain in weight since my first public statement relative to the case, made on Oct. 30th, 1897, has therefore been exactly 4 kilos. (8¾ lb.), as observed on May 10th, 1898, being a total increase of 8·4 kilos (18½ lb.) since the operation. On two occasions there were considerable set-backs in the slowly-increasing series of weights. From the middle of December, 1897, to the middle of January, 1898, there was a reduction of 1 kilo. (2¼ lb.), caused by a severe attack of angina (i.e., tonsillitis or sore-throat) accompanied by high temperatures. The second fall in weight, recorded on May 24th, 1898, was the result of a serious error in diet. Some days previously the patient had eaten excessively of French beans; immediately after doing so she suffered from violent abdominal pain, and for several days she had no appetite. At the end of May her appetite and digestion regained their ordinary condition and her weight rose to 39 kilos. (85¾ lb).

Through her relaxed abdominal walls there cannot at present be felt either a tumour or a spot sensitive to pressure, so that there are no indications of a relapse. The only

Digitized by Google

unusual sensation experienced by the patient is a feeling of pressure in the epigastrium and in both hypochondriac regions after a hearty meal. A quantity of milk amounting to 300 grammes (10½ fluid oz.) or upwards is quite capable of producing this feeling of pressure. The patient also says that she limits her meals from dread of these painful sensations of pressure or tension. Until a short time ago she asserted that she had quite lost the feeling of hunger through the operation, but these two statements do not agree well with one another. The promptings of hunger seem now to be resisted only for fear of the pains which follow too hearty a meal.

In my previous work I have touched upon the various functions of the stomach, which are of course in this case abolished. Dr. Wroblewsky, at that time chemical assistant in the Zürich Medical Klinik, has published his chemical investigations of the patient's urine and fæces in full in the *Centralblatt für Physiologie*, vol. xi., No. 91 (Jan. 8th, 1898); I am much indebted to him for the examination of these excreta undertaken immediately after the operation. He is disposed to regard the remarkably low figures representing the chloride of sodium contained in the urine as an argument in favour of Köppe's view relative to the production of hydrochloric acid in the stomach. According to this theory the hydrochloric acid is not formed from the chlorides of the blood and is not excreted by the gastric mucous membrane, but is formed directly from the chlorides of the food on the surface of the gastric mucous membrane by dissociation of the chloride of sodium and exchange of the sodium-ions and hydrogen-ions of the blood by a process of diosmosis. On account of the absence of gastric mucous membrane no hydrochloric acid is formed in this patient and only small quantities of the chlorides of the food are absorbed in the intestine, so that only an inconsiderable amount is excreted in the urine.

Hofmann,[1] who has in recent months made a series of valuable investigations of the metabolic processes occurring in our patient, does not accept Wroblewsky's explanation of the diminished chlorine in her urine. He was surprised at the retention of chloride of sodium, which, moreover, continued as long as his observations lasted. In addition to ascertaining the chloride of sodium present on each occasion in the separate samples of urine he also determined the total amount of chloride of sodium contained in the fæces, and found that the latter was quite normal in quantity, which proved that the chlorides were absorbed to the normal extent. Hofmann's explanation of the long-continued retention of the chloride of sodium is that the stock of it which is essential for the organism became exhausted during the preceding long period of partial starvation and has not yet been made up to its full amount, and that in particular the extra quantity of chloride of sodium which is, according to Voit, present in the blood of well-fed persons has not yet attained its previous standard. The diminished excretion of chlorine is therefore a favourable symptom in the present case, a proof that the organism is successfully endeavouring to bring its metabolism back to its original healthy condition. Both investigators found a remarkably high acidity of the urine, and both alike observed that the fall in the acidity of the urine which occurs normally after a hearty meal was completely absent in our patient. After dinner the urine is normally either very faintly acid, neutral, or even alkaline. Wroblewsky, however, on the contrary, found an acidity of from 18 to 20 per cent. and Hofmann an acidity even reaching 25 per cent. The difficult micturition after food, which was frequent with the woman, no doubt depended on this high acidity of the urine. The explanation of the fall in the acidity of the urine after food is to be sought in the increased excretion of hydrochloric acid in the gastric juice. In this case there is no production of hydrochloric acid, so there is no fall in the acidity of the urine.

The opinion expressed in my first published statement that the assimilation of the albumin of the food was normal notwithstanding the absence of the stomach, was not at that time supported by any exact determinations of the metabolism. The condition of the patient in the first weeks after the operation obviously did not permit the undertaking of such researches, tending, as they would do, to discourage variety in her diet. Wroblewsky's analyses of the fæces and urine yielded remarkably small amounts of nitrogen and consequently indicated an abundant absorption of albumin. Microscopical examination of the fæces showed not the slightest departure from the normal condition. Moreover, there was the fact that the patient had gained remarkably in weight since the operation. Hofmann has now by an exact estimation shown the results of the absence of the gastric digestion on the assimilation of the albumin of the food. His first series of researches extended over six days and was commenced on Jan. 4th, 1898, four months after the operation. On the first day 1400 grammes (50 fl. oz.) of milk and 5 rolls were given and on the five following days 1540 grammes (55 fl. oz.) of milk, together with the same number of rolls. The fæces corresponding to this diet were of normal aspect, firmly moulded, and appeared in from thirty-six to forty-eight hours after eating. From the nitrogen values obtained for it, which varied between 0·7 and 1·4, and were therefore quite within normal limits, it resulted that "the assimilation of the ingested albumin was very good and that the absence of the gastric juice which acts on albumin made no difference to the assimilation." Hofmann remarks further that "during the six days for which the research was continued the ingestion and excretion of nitrogen did not exactly balance one another, as would have been the case with this number of heat units in a healthy person of corresponding weight. There was a daily retention of nitrogen varying from 0·1 gramme to 1·14 gramme, amounting on the whole to 4·25 grammes and equivalent to 26·5 grammes of albumin and 725 grammes of lean meat (Muskelfleisch). During the six days occupied in the research no increase of weight could be satisfactorily recognised, so that this retention of nitrogen is to be explained as an accumulation of the circulating albumin, an improvement in the condition of the blood which had been greatly impoverished by the previous long-continued cancerous cachexia. The daily retention of, on an average, 0·53 gramme of chloride of sodium gives additional support to the opinion that an increase in the circulating albumin is taking place."

The second investigation of the patient's capacity for assimilation lasted nine days and was carried out a month and a half subsequently with a mixed diet, the daily allowance of which was as follows: 1200 grammes (43 fl. oz.) of milk, 150 grammes (5 fl. oz.) of bouillon with egg, 80 grammes (3 oz.) of fried sausage, 150 grammes (5 fl. oz.) of gruel, 2 eggs, 4 rolls, 20 grammes (¾ oz.) of butter, and 65 grammes (2½ oz.) of whortleberries. In this instance also the mixed diet proved itself to be very well assimilated, for the smallest amount of nitrogen excreted with the fæces was 0·41 gramme nitrogen in 11·6 grammes fæces, while the largest was 2·06 grammes nitrogen in 49·9 grammes fæces. These figures being quite normal demonstrate that, so far as this question is concerned, the absence of the functions of the stomach does not make itself seriously felt. Furthermore, an investigation of the conditions of assimilation of the fatty part of the food confirms my previous statements. With a daily consumption of fat averaging 84·5 grammes there was a daily excretion of fat averaging 4·64 grammes; the loss was therefore only 5·5 per cent. of the whole, so that the assimilation could not have been better under any circumstances.

Hofmann draws from these results the practical inference that it is a mistake to allow no more than the least possible quantity of food to patients suffering from chronic disease of the stomach, and that the failure of nutrition and strength manifested by such patients is in most cases brought about by the regimen to which they are subjected even more than by the disease itself. With regard to this inference it should be remarked that it can only find practical application when it is at the same time possible to shut off the affected organ from the digestive tract. To give the quantity of food ordinarily taken would hardly be an advantage, for it produces considerable mechanical irritation, especially in certain cases which have to be regarded from a therapeutic point of view, and it often will not pass from the stomach into the remainder of the digestive canal.

Although the previous daily examinations of the urine and fæces for putrefaction products enabled me to give a reply in the negative to the much-debated question whether the hydrochloric acid of the stomach has any influence or not over the processes of putrefactive decomposition of food products in the intestine, the more elaborate investigations made by Hofmann at a later period were nevertheless valuable to me. The food given to the patient during the earlier observations was selected with a definite object and was not particularly liable to undergo putrefactive changes. Hofmann ascertained the amounts of A and B sulphuric acids in the urine for fifteen consecutive

[1] Hofman: Observations on Metabolism after Total Resection of the Stomach, Münchener Medicinische Wochenschrift, No. 18, 1898.

Digitized by Google

days. The patient's food consisted principally of milk, different kinds of animal food, three or four eggs, soup, gruel, and rolls; the quantity of milk was from 500 c.c. to 700 c.c. (17½ fl. oz. to 25 fl. oz.) and that of animal food from 100 to 150 grammes (3½ oz. to 5 oz.). On the third and fourth days she took 300 c.c. (10½ fl. oz.) of kephir (partially fermented milk) instead of 300 c.c. of ordinary milk in order that the subsequent fall in the ethereal sulphates might be watched. From the sixth day onwards she took in addition 50 grammes (1¾ oz.) of old Gervais cheese and afterwards about 30 grammes (1 oz.) of Liebig's peptone, substances abounding in putrefactive germs, albumin, and casein, from which a certain amount of increase in the putrefaction processes was to be expected. Finally, 20 grammes (¾ oz.) of butter were added, for with fatty diet there is an enhanced excretion of ethereal sulphates. From the comparison of his results it appears that the daily value of the ethereal sulphates varied between 0·086 gramme (on the first day of taking the kephir) and 0·165 gramme (on the second day of taking the peptone). By these figures it is proved that the entire absence of the gastric juice, charged as it is with hydrochloric acid, is without any influence on the extent to which putrefactive decomposition is developed in the intestine, since the values found for the (ethereal) sulphuric acid are less than those which occur normally (about 0·20 gramme). Hofmann concludes from this that it is useless to prescribe hydrochloric acid with the view of disinfecting the intestine, although this plan is often proposed and carried out in practice, for even the hydrochloric acid abundantly poured forth by the stomach, the quantity of which is not approached by the amount ordinarily prescribed, may be entirely absent without any increase in the putrefactive changes in the intestine.

I am indebted to Dr. Otto Veraguth of Zürich for a further series of valuable researches on theoretical and practical points, which researches he has in the kindest manner handed over to me for publication. In the year 1896 there appeared an article by Dr. Tschlenoff[2] the title of which was "Der zeitliche Ablauf der Stickstoffausscheidung im Harn nach einer Mahlzeit" (The Successive Stages of the Excretion of Nitrogen in the Urine after Food), and in which it was shown, contrary to what was previously supposed, that the excretion of nitrogen after the taking of food rich in albumin could not be represented by a line gradually rising and then falling, but that the curve of hourly elimination contained *two* maximum points, the first from two to four hours and the second from five to seven hours after the taking of the food; the first maximum is followed by an obvious decline and a subsequent rise to the second maximum. Experiments with peptonised food brought the first maximum very plainly into view. Dr. Tschlenoff believes that these facts must be explained on the assumption that the quick rise of the curve in the first two or three hours is due to absorption in the stomach and that its decline in the fourth and fifth hours is to be referred to the passage of the acid chyme into the intestine, where it is neutralised and digested, whilst the second rise of the curve is in connexion with the active absorption in the intestine.

From these results Dr. Tschlenoff drew the following conclusions: "Nitrogen determinations made every hour after taking food give us some insight into the conditions of digestion and absorption in the stomach and intestine respectively, since we can from inspection of the nitrogen curve recognise the separate action of the stomach and the intestine. The curves yielded by animal food and by peptone differ essentially from one another, for the peptone curves are almost entirely curves of absorption in the stomach. If the processes of digestion and absorption which take place in the stomach are disturbed the nitrogen curve loses its regular contour. Hourly determination of the nitrogen in the urine after the ingestion of ordinary animal food and of peptone may under certain circumstances be employed as a means of diagnosis in diseases of the stomach."

The importance of these questions induced Dr. Veraguth a short time afterwards to repeat and extend Dr. Tschlenoff's experiments, and the results obtained by him have appeared in the *Journal of Physiology*[3] under the title "The Effect of the Meal on the Excretion of Nitrogen in the Urine." In his first group of experiments Dr. Veraguth examined the urine every hour after the taking of food containing variable amounts of albumin. Without being affected by this last-mentioned circumstance the curve always assumed such a form that on an average the first maximum occurred in from two to five hours and the second in from four to eight hours. His experiments therefore confirm Dr. Tschlenoff's results, but Dr. Tschlenoff's explanation that the first maximum corresponds to an absorption of the albumin of the food by the stomach necessitated at the least a following up of the question according to a modified plan. Moreover, his opinion with respect to the amount of the absorption of albumin in the stomach is not in harmony with current scientific views. In a second group of experiments an attempt was therefore made to arrive at an exact analysis of the first rise of the curve by causing the person to pass urine at shorter intervals of about half an hour or a quarter of an hour after taking food containing amounts of albumin which varied from time to time, the underlying idea being that secondary (*reflectorische*) processes occurring in the body after food were very probably responsible in part for the form of the urea excretion curve. Harley's experiments with Mosso's ergograph have proved that there is an immediate increase of muscular power after taking food. Might not, therefore, the taking of food equally well give a secondary impulse to the metabolism as a whole and consequently to the excretion of urea and nitrogen in the urine? This conjecture made by Dr. Veraguth found its confirmation in the second group of experiments, but only to the extent that a quarter of an hour or half an hour after taking food a third rise in the curve was discovered, not so high as those already mentioned, but very constant. This rise can hardly be regarded as other than secondary, but the question whether this mysterious second elevation of the curve corresponded to absorption of albumin by the stomach was nevertheless as far as ever from being answered. Control experiments in a person without a stomach were therefore exceedingly valuable for the solution of this question.

Dr. Veraguth's description of his investigation has been placed at my disposal in the most disinterested way and may be re-stated here with a few abbreviations. "The patient passed urine at 6 A.M.; the urine was measured and a sample preserved. At 7 A.M. there was a second emptying of the bladder, measuring of the urine, and setting aside of a sample. Then the patient took her breakfast, consisting of eggs, rolls, and milk. At 8 A.M. she passed urine again, and so on until 12 noon, and on a subsequent occasion until 2 P.M. The observations were not at first carried further because the experiment, which in itself was harmless even for this particular individual, might have been made serious by longer fasting. It was only on the concluding day (May 20th, 1898) that they were continued to 4 P.M., which could be done without risk on account of the patient's remarkably good condition. In the intervals she drank tea without milk whenever so disposed in order to relieve her thirst and promote diuresis. Half-hourly or quarter-hourly collections of urine could not be arranged for as the patient was not equal to such frequent urination. The urea was determined by the Knop-Hüfner nitrogen method,[4] which consists in decomposing the urea into carbon dioxide, water, and nitrogen, by shaking a measured quantity of urine with solution of sodium hypobromite. The carbon dioxide and water are immediately absorbed by the solution, while the nitrogen remaining free is measured and is multiplied by the coefficient 0·002683 in order to calculate the urea. The volume of the nitrogen was not reduced to 760 mm. (30 in.) atmospheric pressure and 0° C. (32° F.) temperature, as the analyses were made within a moderate compass of time and therefore without important variations in the pressure and temperature. Dr. Tschlenoff has laid stress on the applicability of the method to these experiments, but as a matter of fact it is, when taken by itself, very inexact; in the present case, however, the object was only to obtain relative values—namely, the comparison of the quantities of urea from one hour to the next.

Observation I. (Jan. 29th, 1898).

Time.	Amount of urine.	Nitrogen.	Urea.
	c.c.	c.c.	Grammes.
6 A.M. (night's urine). (Then a cup of tea without milk.) ...	600	8·0	13·8
7 A.M. (breakfast: 2 eggs, 1 roll, milk)	—	—	—
8 A.M.	65	10·0	1·74
9 A.M.	100	1·8	0·48
10 A.M.	300	3·8	3·05
11 A.M.	100	6·0	1·00
12 NOON	45	8·0	0·94

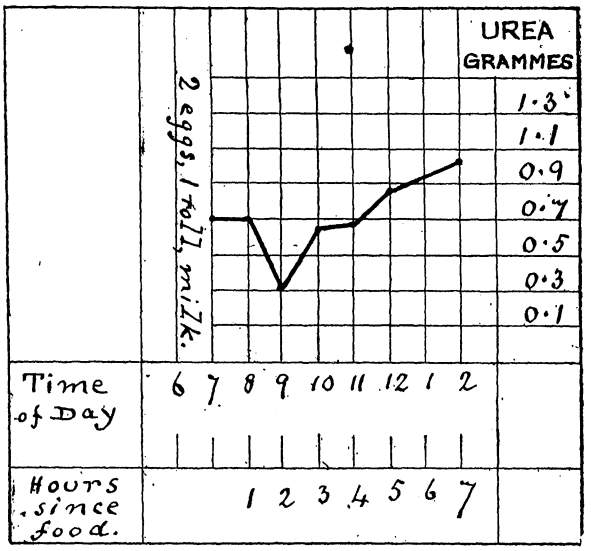
With a view to this experiment the patient drank a cup of tea at 6 A.M. in order to excite diuresis. At 7 A.M. she had her breakfast, consisting of two eggs, one roll, and about one-third of a litre (12 fl. oz.) of milk; it therefore contained a tolerably considerable quantity of albumin and casein. The night's urine, voided at 6 A.M., measured 600 c.c. and yielded 8·0 c.c. nitrogen, which corresponded to 13·8 grammes urea. Unfortunately the patient was not able to micturate again at 7 A.M., so that the next sample (collected at 8 A.M.) contained the nitrogen excreted immediately before and after the food. This, however, did not seem to have any important effect in vitiating the course of the curve, for it continued to descend during the next hour—the second since the food—the urea falling to 0·48 gramme. After that, however, in the third hour there was a sudden rise of the urea to 3·05 grammes, in the fourth hour a fall to 1·00 gramme, and in the fifth hour a further fall to 0·94 gramme. In other words, a patient whose stomach has been removed exhibits three hours after a meal a very decidedly increased excretion of nitrogen, followed by an equally obvious decrease, a sequence which appears to be usually the case also in normal individuals. (See Fig. 1.)

FIG. 1.

Curve showing hourly excretion of urea (Jan. 29th, 1898). Apparently the words "1 cup of tea" ought to be read as on the 6 A.M. line, and the words "2 eggs, 1 roll, milk" as on the 7 A.M. line.



An account of Observation II. is not obtainable, as circumstances unfortunately prevented the work from being completed.

Observation III. (Feb. 16th, 1898).

Time.	Amount of urine.	Nitrogen.	Urea.
6 A.M.	115	?	?
7 A.M. (Breakfast: 2 eggs, 1 roll, 400 grammes milk)	105	2·5	0·70
8 A.M.	60	4·5	0·72
9 A.M.	600	0·2	0·33
10 A.M.	300	0·8	0·65
11 A.M.	100	2·5	0·67
12 NOON	80	3·8	0·81
1 P.M. (Tea)	—	—	—
2 P.M.	100	4·0	1·07

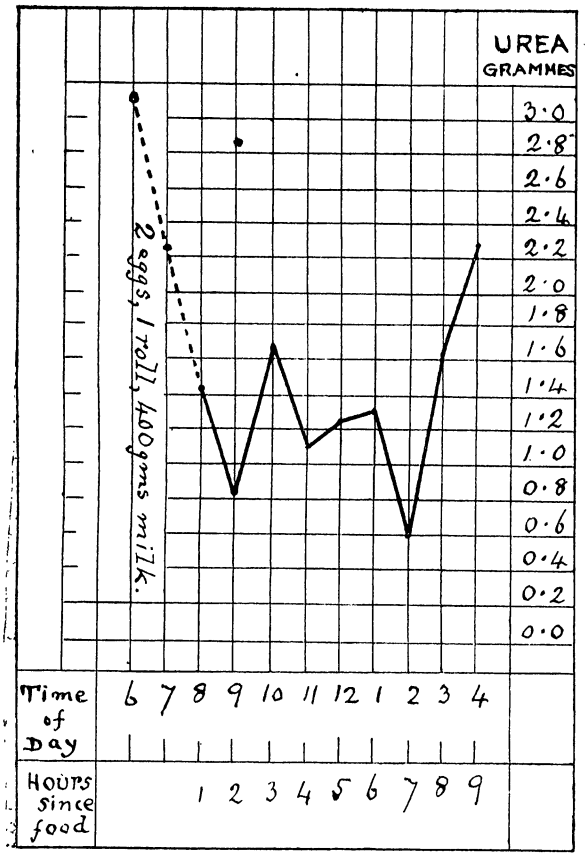
The food in this case was the same as in the preceding one, and in it similarly there was after the second hour a sudden change of direction in the previously falling curve, which did not fall after that period, but maintained itself at the same level during the fourth hour, subsequently rising until the observation was concluded at 2 P.M. Unfortunately the patient did not micturate at 1 P.M., so that whether this rise was really uninterrupted or not must remain an open question. (See Fig. 2.)

FIG. 2.

Curve showing hourly excretion of urea (Feb. 16th, 1898). Apparently the words "2 eggs, 1 roll, milk" ought to be on the 7 A.M. line.

It will be seen that although the amounts of albumin ingested in Observations I. and III. were similar, yet the curves show that in each case taken by itself very different quantities of nitrogen were reported—a discrepancy which has been pointed out in previous investigations under normal conditions of the alimentary canal. The essential thing, however, to be kept in mind just now is the fact that in this case, exactly as in a normal individual, the elimination of nitrogen undergoes a notable increase two hours after meals.

Observation IV. (May 20th, 1898).



Time.	Amount of urine.	Nitrogen.	Urea.
6 A.M.	100	11·5	3·08
7 A.M.	80	11·4	2·23
8 A.M.	65	8·1	1·41
9 A.M.	75	4·2	0·84
10 A.M.	105	6·0	1·68
11 A.M. (One cup of tea.)	80	5·3	1·14
12 noon	90	5·1	1·23
1 P.M.	70	7·2	1·32
2 P.M.	110	2·2	0·59
3 P.M.	135	4·5	1·63
4 P.M.	170	5·0	2·28

The food taken on that day agreed exactly with that which was taken during the previous observations, consisting as it did of two eggs, one roll, and 400 grammes (14 fl. oz.) of milk; at 11 A.M. the patient drank a cup of tea. Urine was passed hourly till 4 P.M. It might perhaps be thought that by reason of their too short duration the foregoing observations had not given absolutely unequivocal curves, for the increase of urea appearing in them from two to three hours after food ought, in an individual who had no stomach, to correspond not to Dr. Tschlenoff's first maximum but to the second maximum, which he supposes is due to absorption in the intestine. However this may be the present curve leaves nothing to be desired in respect of clearness, that is, in respect of agreement with the curves obtained under normal conditions. In

Digitized by Google

the third hour after food it rises to a first maximum, then sinks with oscillations to the seventh hour, and in the eighth and ninth hours rises suddenly to a second maximum. In other words, it is an excellent copy of Dr. Tschlenoff's curve. (See Fig. 3.)

FIG. 3.

Curve showing hourly excretion of urea (May 20th, 1898). Apparently the words "2 eggs, 1 roll, 400 gms. milk" ought to be read as on the 7 A.M. line.

This patient's case must therefore be taken as proving with absolute certainty that the successive stages of the excretion of nitrogen in the urine after food are quite independent of gastric digestion, because removal of the stomach from the digestive tract does not cause the excretion curve to deviate in any way from those which are obtained under normal conditions.

Notwithstanding these extremely instructive observations on our patient, it unfortunately still remains an open question which organs give the curve of nitrogen excretion its characteristic form. This much, however, is certain, that the stomach is not responsible for it, that Dr. Tschlenoff has not given the right interpretation to his very interesting results, and that hourly determination of the nitrogen in the urine after taking meat and peptone is not to be relied on as a means of diagnosis. It is to be hoped that Dr. Veraguth's indefatigable exertions in this field of inquiry may very soon supply incontestable scientific evidence to confirm his hypothesis relative to the excretion curve of nitrogen.

Postscript by Dr. Schlatter.—After the completion of the foregoing observations I received news of another successful case of total extirpation of the stomach. Induced by the account of my case which appeared in the *Medical Record* (New York) of Dec. 25th, 1897, Dr. Charles Brooks Brigham of San Francisco on Feb. 24th, 1898, removed an entire stomach affected with carcinoma, the patient being a woman sixty-six years of age.[5] He succeeded in uniting the duodenum to the œsophagus. Seven weeks after the operation the patient's condition was in every way satisfactory.

[5] Case of Removal of the Entire Stomach for Carcinoma; Successful Œsophago-duodenostomy; Recovery. Boston Medical and Surgical Journal, May 5th, 1898.

A CONTRIBUTION TO THE SURGICAL TREATMENT OF PHTHISIS OF THE APEX.

BY NORMAN PORRITT, L.R.C.P. LOND., M.R.C.S. ENG.,
HONORARY SURGEON TO THE HUDDERSFIELD INFIRMARY.

THAT phthisis may be treated surgically has been the hope of many besides the writer of this article; and when the natural history of the disease is studied, when its physical signs are considered, when some of the cases which have been seen are recalled to mind and the subject is illuminated with the light of clinical experience, and when the lessons of the post-mortem room are learned aright, it is felt that the hope is not altogether unjustifiable. For above all things phthisis is a curable disease. One is too apt to look upon it as a hopeless affection, less to be dreaded tha cancer perhaps but for its ultimate result equally to be feared. But not only does phthisis respond to treatment as readily as most other affections, but much more readily than many, whilst the records of the post-mortem room show that many phthisical lesions of the lung end in actual cure.

The achievements of surgery have put beyond question the curability of tubercle. Even diffuse abdominal tuberculosis is curable in a number of cases by a simple surgical operation; and no message comes to us in clearer language than that which tells us that it is to local treatment we must look for our greatest triumphs over tubercle. From the joints, the cervical glands, the viscera, and the peritoneum the message comes with unwavering certitude and emphasis. Moreover, we have in the lungs a local condition which explains not only why so many lung lesions heal and so many cases of phthisis show such remarkable improvement, but a condition which is one of the best auguries for the after-success of any local operative measures. For readiness to heal wounds of the face are pre-eminent, the explanation being that the blood-supply of the face is so lavish—lavish in the freedom of anastomosis as well as in the supply of vessels. But the lavish blood-supply of the face is not to be compared with the exuberant network of the lungs. The tendency of all lung lesions is to heal, and for that tendency they have to thank the prodigality of their blood-supply. The tendency of lung lesions to heal is constantly exemplified in all but cases of acute phthisis. Some time ago I wrote the death certificates of two cases of phthisis which had been under my observation more or less for between five and six years. In each case the whole of that period was marked by periodical disablement and recovery of the patient. From some cause, perhaps a chill, the patient would be confined to his bed or room and after a variable period would emerge to take up the duties of life as before. So complete, indeed, were some of the recoveries from these exacerbations that the patients believed themselves quite well until a further breakdown disillusioned them. This characteristic of phthisis is too common to need any other remark than that the more acute the disease the less marked are the remissions or, as I prefer to call them, the attempts at healing. But for this tendency on the part of the lung to heal few cases of phthisis would survive many months, and hæmoptysis would be one of the most fatal and dreaded events. But when on examining a case of phthisis we find flattening of the chest-wall from retraction of the ribs and interspaces, we know that whatever may be the destructive process which is going on within, a degree of healing—not perhaps sufficient to cure the disease and bring the case within the category of the cured, but enough to postpone the fatal event and give the patient a few more years or months of life—is taking place; for sinking of the chest-wall is the inevitable result of the shrinking of the lung. A destructive and a reparative process are going on side by side. On the one hand there is loss of substance; on the other hand, healing and contraction of the cicatrix, if I may be allowed to use the word in this connexion. That the process is as much reparative as destructive is evident from the extreme contraction sometimes seen. In the case of a woman, aged twenty-nine years, who came to my out-patient room on Feb. 26th, 1895, the whole of the upper part of her right chest in front above

Digitized by Google

the fourth rib was shelving and flattened. Over the whole of the area indicated quite up to the sternum was a deep depression, the sternum being very prominent and the joint between the body and the manubrium quite pointed. This area was quite dull, and even on deep inspiration there was very little movement in it. Except at the extreme apex where the breathing was tubular and amphoric, the respiratory sounds were very faint, with prolonged expiration. The patient gave a history of three years' illness, and it was not the right lung which caused her to seek aid, but the outbreak of phthisis in the left. I saw this patient on only one other occasion, and I assume that the trouble in the left lung soon incapacitated her from further attendance, notwithstanding the desperate attempt made by the right lung to heal and cure itself.

Having learnt, on the one hand, that lung lesions heal and, on the other hand, that they make attempts which end almost in success, we shall not be surprised to learn that surgeons have endeavoured to give them additional help by applying to them principles successful in other parts of the body. The measures adopted may be divided into excision of portions of the diseased lung and opening and draining of cavities.

Dr. Lowson of Hull has excised the right apex of the lung of a woman, aged thirty-four years,[1] and the patient recovered with a sinus. I am not aware that he or anyone else has repeated the operation in the human being, and many additions to our experience and knowledge of pulmonary surgery will have to be made before such an operation, with its obvious risks, can find a place among orthodox surgical procedures.

And when we turn to the treatment of phthisical cavities we are met by difficulties which, even at the present time, cannot be said to have been surmounted. In theory beautiful and simple, the attempt to open and drain a pulmonary cavity is in practice difficult and uncertain, for the determination of the character of an excavation of the lung must be as precise as the definition of its position must be exact. It may answer the requirements of the physician to put his finger on the chest wall and say the cavity lies here. Whether it does or not no harm is done, and the efficiency of his remedies will not be jeopardised. But a mistake of half an inch in the location of a pulmonary cavity may foil a surgeon and baffle all his efforts; and even if he hit the excavation he may find that he has opened not a cavity, but a honeycombed space which it is impossible properly to deal with in the cramped narrow space within which he has to conduct his manipulations, even though some of the ribs may have been removed. If a cavity is near the surface, if it is a cavity and not a molecular breaking down of the lung, if its limits can be clearly defined and the information gained by physical examination can be confirmed by the use of the exploring needle, it may be within the scope of successful surgical interference. But few phthisical cavities realise this ideal condition. More than one attempt to reach phthisical excavations at the apex are recorded in the medical journals with barren results, for it would seem that the conduction of sounds through the lung has caused physicians to locate and operators to cut down upon places where no cavity was. Moreover, in most phthisical cavities the exploring needle gives no help; the ribs are an ever-present hindrance, and notwithstanding the admirable results of Mr. Godlee, I think we may sum up this section of our subject with the conclusion that the treatment of phthisical lesions of the lung by drainage is an attempt to attain that which with few exceptions has thus far proved to be the unattainable.

On one point, however, I have no doubt, and that is that if drainage of cavities of the apex is to be successful it will have to be undertaken, not from the front, as has hitherto been the case, but from behind. If an incision be made above the scapula over the most prominent part of the ribs portions of the second and third ribs are easily removed, and the finger finds itself in a cavity the roof of which is formed by the first rib with the pulmonary apex below it. This is the most direct and sure route to the apex of the lung. But comparatively easy as the operation is on the dead body it is, from the depth and confined limits of the wound, impossible in the living subject to deal with the affected lung. I have twice attempted to do so without success. We see, therefore, that the help the surgeon has been able to give to phthisical lungs is insignificant compared with the inherent power of the lung to help itself. Drainage has been a comparative failure, and the removal of a diseased portion of lung is not an operation which can be considered within the practicable bounds of accepted usage. It is evident, therefore, that any new procedure must be upon fresh lines.

We have seen that not only can phthisis be cured, but that it makes prodigious attempts to cure itself. Let us try to discover—if we can—why it so often falls just short of doing so. Why does the lesion, surrounded as it is with an abundant supply of nutritive material, not heal? I venture to suggest that the reason, the reason of all, is a mechanical one. The damaged and diseased lung shrinks as far as it can, drawing in the ribs and distorting the chest in the manner which is familiar. If the lung were surrounded with a wholly fleshy case instead of a rigid bony framework we should have many more examples of healed phthisical lesions to add to those found in the post-mortem room. The lung becomes adherent to the chest wall and the unyielding ribs hold the walls of the cavity apart. We see nature—I use the word for want of a better—doing her best, the lung contracting as far as it can and the phthisis becoming for the time arrested. Some cases, such as that of my out-patient previously referred to, would heal but for the ribs, and I venture to think that this is an instance where we ought to return the lead which nature gives us and endeavour to place the lung in such circumstances that the healing process may be carried to the fullest possible extent. I propose, therefore, that portions of ribs should be removed both back and front from the upper part of the chest. Two soft, yielding surfaces are formed with a loose length of rib between. The area from which the portions of rib are taken is now free to follow the contracting and healing lung, whilst the floating pieces of rib can be drawn bodily towards the spine or in any other direction that the shrinking lung takes. They are, in fact, loose fragments lying upon the soft tissues instead of, as before, part of a hard framework supporting and holding the soft, fleshy structures. I have now done the operation in three cases and have suggested it in a number of others, but when the almost inevitable improvement has begun most of the patients have been glad to shun the bugbear of an operation, being buoyed up with the fallacious hope that they were getting better. Three patients gave their consent to operation and afterwards withdrew it, and in the case of others disease in the other lung supervened before I saw my way to make definite proposals for the operation.

CASE 1.—A man, aged sixty-five years, was admitted to the Huddersfield Infirmary on July 7th, 1893. He was a thin, spare man with a fresh-looking, healthy complexion. Nine months previously he caught a cold and had had a cough, with spitting of thick, yellow phlegm, ever since. For some years he had been short of breath. There was no pain. He spat most freely from 6 to 9 A.M. There was no hæmoptysis, but he had lost weight during the last nine months, whilst the appetite had been very poor. With regard to the chest the right side was flattened, especially in the infra-clavicular region. Expansion on both sides was poor, especially on the right. On the right side, except over the second rib in front, there were impaired resonance, especially at the apex, with feeble breath sounds, and over the middle and lower lobes coarse crepitations. In the regions of the second rib the resonance and vocal fremitus were increased. On the left side there was vesicular breathing throughout, with marked and prolonged expiration. The heart was healthy. On July 10th the anterior portions of the second and third ribs were removed through an opening in the pectoralis major along the course of the second rib. A drainage-tube was inserted from the axilla. Portions of the same ribs were removed from behind through an oblique incision at the posterior and upper part of the upper aspect of the chest. The patient bore the operation well and the drainage-tube was removed on the third day. He was discharged on Nov. 3rd, four months after his admission. His long stay in hospital was caused by the continued suppuration of the cavity below the pectoral muscle. No dressing seemed to check the too abundant discharge and the patient would not for a long time consent to a further surgical operation, and when at length he did so and the wound was opened up a piece of gauze, which had found its way into the wound cavity unperceived, was found. On its removal the wound slowly healed. On leaving the hospital he was ½ lb. heavier than on admission. He attended periodically

as an out-patient till July, 1895, when from increasing weakness he was unable to make the journey of 10 miles to the hospital, with a walk of over 2 miles between his home and the village station. On Nov. 6th, 1895, two years after he left the hospital, I saw him at his home. He looked greyer and thinner. The pulse was 84 and of fair strength, the respirations were 27, and the temperature was 98·9°F. He was spitting thick, muco-purulent, stiff phlegm, in which there was no blood. He slept badly and coughed a good deal, but it was not the cough which interfered with sleep. As to his chest, immediately below the right clavicle was a quadrate gap measuring 4½ in. across and 4⅜ in. from above downwards. When he inspired this gap did not move at all. The supra-clavicular space was sunken and dipped down behind the clavicle obliquely—almost perpendicularly if he stood up—1⅝ in. The hand sank behind the clavicle into this hollow in a remarkable manner. Near the shoulder the gap below the clavicle was no bigger than on the opposite side; but, unlike the other side, on which the rounded barrel of the chest at once came to the front, the gap sank till near the sternum. The movement throughout this lung was very small indeed, and in the gap there was none at all. The first rib could be felt most perceptibly bordering it, with a rounded prominence at the extreme inner and upper corner. It was difficult to decide whether there had been renewal of bone after the removal of the portions of ribs. The whole floor felt hard, but there was no continuation of any ribs from either of the cut ends. The pectoralis major seemed adherent throughout, but this was probably due to the long-continued suppuration from the retained dressing and ought not to occur in another case. The depth of the cavity, ascertained by measuring from a sheet of stiff paper laid across it, was exactly 1 in. Percussion over the whole of the upper part of the right lung gave a dull note. There was increase of fremitus as well as of vocal resonance, especially in the middle of the cavity. Behind, the right lung was completely dull above the spine of the scapula, and below the resonance was much impaired. Râles and rhonchi were heard over the lower part of the right lung, but above the level of the lower margin of the parietal depression no breath-sounds could be heard. The left lung was hyper-resonant except at the extreme apex, where it was dull, and bronchial râles were heard pretty generally all over it; in addition there was cavernous breathing for a space of three fingers' breadth below the dull area at the apex. The patient died on May 13th, 1896, having lived six weeks short of three years after the operation. As I did not hear of his death till several weeks afterwards no post-mortem examination was possible. Nor had I the opportunity to take a plaster cast of the condition of the chest, for the patient would not permit me to do so during his lifetime. I regret this the more as words cannot convey an adequate impression of the remarkable condition to which it attained. I can only say that neither before nor since have I seen anything approaching it, the depth of the gap and its absolute immobility during respiration being scarcely conceivable.

CASE 2.—A girl, aged fifteen years, was admitted to the Huddersfield Infirmary on Dec. 11th, 1896. Four months previously she had vomited "enough blood to fill a two-pint jar" and was in bed for a month. Since then she had had night sweats, loss of flesh, and cough without much expectoration. Her father was dead, but the patient had not been ill before the present illness. There was dulness in the left infra-clavicular region, with coarse râles over the whole of the left side and marked tubular breathing near the apex of the left lower lobe behind. Both apices expanded indifferently, whilst the respiration generally was markedly abdominal and the movement of the chest on respiration was much impaired. At the inner end of the right clavicle cog-wheel breathing with a few moist râles were heard. On Dec. 13th portions of the four upper ribs were removed. An oblique incision was first made beginning between the spine and the upper part of the scapula and with much difficulty portions of four ribs were removed. The pleura was opened several times. Through an incision along the lower margin of the pectoralis major portions of the second, third, and fourth ribs were removed from the front of the chest. The patient bore the operation badly and on the second day incessant vomiting came on and she died the same day. No post-mortem examination was allowed. In this case I think I unwittingly took away a portion of the first rib posteriorly and probably injured some of the important nerves passing over it.

CASE 3.—The patient was a man, aged forty-seven years. He had been very unsteady, had had influenza three years ago, and had not been well since. For a year he had been attending as an out-patient. His shoulders were rounded and he complained of cough and loss of flesh. The left side of the chest was flattened in front, with dulness from the supra-clavicular region to the cardiac area. Behind there was dulness on the left side from the seventh cervical to the fourth dorsal vertebra. Over the dull area the breath-sounds were diminished and there was cog-wheel respiration over the lower part of the left lung and at the right apex. On March 29th, 1897, ether was administered and through an incision along the lower border of the pectoralis major portions of the second, third, and fourth ribs were removed from the left side of the front of the chest, the ribs being divided as far back as possible in the axilla. The patient took ether very badly and the removal of portions of rib from behind was deferred. There was a good deal of pain after the operation, and on the following day the temperature went to 104·4° F., but the wound when dressed the following morning looked well and the patient complained of nothing but a somewhat troublesome cough. On April 5th he began to ramble at night, signs of pneumonia at the left base subsequently developed, and he died on April 12th. At the post-mortem examination 3 oz. of pus were found in the left pleural cavity. The left lung was adherent throughout and its lower lobe was a mass of red hepatisation. The wound cavity was unhealed and much shrinking of the lung had taken place already.

In the last two cases the anterior incision was made along the lower border of the pectoralis major and the portions of ribs were removed from beneath the muscle. This, however, is a more difficult plan than that of cutting through the muscle straight down to the rib. Nor should I again begin at the posterior aspect of the chest. The ribs approach very close to each other here and it is difficult to apply either cutting forceps, rib shears, or saw in the narrow interspaces. After the ribs are divided in front they move much more readily and the insertion of the blade of the forceps or shears is facilitated. The death of the patient in Case 2 was, I think, attributable to the difficulties encountered by attempting to deal first with the posterior aspect of her chest. She was a delicate girl, not well fitted to bear an operation, which proved unexpectedly tedious as well as dangerous from the admission of air into the pleural cavity and probable interference with important structures in the neck. In subsequent cases these dangers ought to be, and can be, avoided. The patient in Case 3, who died a fortnight after the operation, was a broken-down, dissolute man, who was cast off by his friends. I had suggested the operation to him nearly a year before he had it done. He was not a good subject for any operation, and I did it at his own request, after explaining to him that I could not promise that he would survive the ordeal.

In the case of the other patient (Case 1) there can be no doubt that the operation prolonged his life, whilst the local effects upon the chest and its contents show that the theoretical aim of the operation is capable of practical attainment. After leaving the infirmary the man went back to his home and received only the attentions to be obtained in the home of a cottager in the humbler walk of life. The case was one of fibroid phthisis and not one of tuberculosis, and whilst it may be premature to draw the conclusion that a case of tuberculous phthisis would show so marked a degree of contraction after removal of portions of ribs the case proves that where fibrosis is going on the ribs are an obstacle which will check its fullest possible development. And when we remember how large a share fibrosis has in the arrest of chronic tuberculous phthisis the result attained in the case of my patient suggests that a method lies before us of making the degree and effects of fibrosis still more complete and beneficent. By allowing this process to have fullest scope we strangle the disease by cutting off its blood-supply, and the operation may be compared in its mode of action to the treatment of a growth by ligaturing the vessels. Moreover, the effects of the check to the blood-supply of the lung and the physiological rest which the affected area receives are augmented by the state of functional inactivity to which the area of lung is reduced. The portion of lung, in fact, ceases to be of any use as lung, is brought into a carnified condition, and merely fills the space of the body and chest which it occupies. No attempt whatever is made to touch the lung. The operation is entirely extra-pleural.

Digitized by Google

It is an operation which can be done deliberately and all the manipulations are conducted within sight. Removal of ribs has been practised for long-standing empyema, and in suitable cases is a useful procedure, though the *rationale* of the operation in phthisis and empyema is not quite similar. In empyema portions of ribs are removed from the wall of the cavity so that the chest may meet the pleural surface of the healthy lung and the lung ultimately re-expand. In removal of ribs for phthisis the object is to promote the contraction of an already cicatrising lung. When air is admitted to the pleura the lung as a rule collapses and carnifies. The lung may be compared to an indiarubber cricket-ball permeated with air and constantly tending to return to its solid state. If it were not for the ribs the act of respiration and the pressure of the atmosphere would reduce the lung to a semi-solid mass. And we know from cases of atelectasis in the newly born when once the process has begun how quickly it goes on to a fatal issue. When adhesions have obliterated the pleural cavity—as they do in most cases of phthisis—removal of the ribs brings this atmospheric pressure to bear almost directly upon the lung beneath, and in addition to the contraction of the lung itself we have the additional aid of atmospheric pressure to ensure the collapse of any healthy lung which may be present around the focus of the disease.

It is not necessary to touch the first rib, and possibly the fourth may be left. Phthisis rarely begins at the extreme apex of the lung, and the shrinkage which will take place after the removal of portions of the second, third, and fourth ribs will be enough for the purpose. In the successful case the apex has fallen in at least one inch. Now an inch of contraction of the apex is worth two or three inches over the middle lobe. If in this narrow strip of lung we can get an inch of contraction—in young subjects with more supple tissues we ought to get more—we place the lung in those circumstances which are favourable to the fullest possible measure of the curative contraction.

Phthisis is usually spoken of as most commonly occurring at the apex of the lung; in other words, at the upper part of the upper lobe of the lung. In this connexion it is important to remember the wide area of the upper lobe which comes to the front. The right upper lobe in front fills the space between the clavicle and the diaphragm, whilst the upper lobe of the left side dips down for a very considerable distance into the axilla. We are apt on hearing the physical signs of phthisis extending more or less generally over the front of a patient's chest to assume that the whole of the lung is involved. But this is by no means necessarily the case. If we find at the posterior aspect evidence of disease only at the upper part of the lung we may be tolerably sure that one lobe only is implicated and that the disease has not spread to the body of the lung. This anatomical fact would explain those apparently hopeless cases of phthisis which, to our surprise go on from month to month and even from year to year, when according to the physical signs dominating the front aspect of the chest they ought to have been dead long ago.

Having seen, on the one hand, the help which we can give a contracting portion of lung by removal of the ribs over it, we see now that we have the very part of the lung prone to phthisis almost beneath the ribs which are most easily dealt with. Desirous to ascertain what extent of lung surface could be easily exposed I examined the body of a woman who, with the exception of a fibroid tumour and ruptured pyosalpinx, from which she had died, was healthy. The trachea having been tied 2½ in. of the second, third, and fourth ribs were removed, beginning close to the cartilages. An area of 2½ in. by 5¾ in. was exposed, reaching from the clavicle above to the lower limit of the chest below, for the upper border of the fifth rib was the boundary of the area below. The first rib projects so little upon the front of the chest as to make but an insignificant encroachment upon the exposed space. With the lung still *in situ* the outline of this space was marked upon it with a knife and the lung was then removed. It was not difficult to understand, after examining it, that the removal also of portions at the back of the apex would leave the affected part of a phthisical apex free scope to contract to an extent sufficient to permanently arrest the disease.

We have to remember that by encouraging carnification we are bringing about a condition unfavourable to the development of tubercle. It is said that tubercle rarely attacks a lung compressed by fluid in the pleura and by promoting the contraction and collapse of the affected lung we are putting the lung into a state less favourable for the development of tubercle than it is naturally, for the lavish blood-supply is a sword with a double edge—it hastens the spread of tubercle as well as supplies the nutritive material for the healing forces. On the other hand, whilst carnification and cicatrisation of the lung are destructive of tubercle by modifying the soil in which the tubercle is planted, they do not interfere with the healing process, because they are an integral part of it.

Writing three years after the date of my first operation Dr. Stuart Tidey,[2] in proposing strapping of the chest in cases of phthisis, says: "The suggestion to strap the chest in phthisis is invariably met with the objection that one of the objects of treatment in that disease is to expand the chest and so call into play portions of lung which in conditions of sub-active health take little or no share in the respiratory process. This objection does not recognise the change in the mechanical conditions of respiration produced by diseases of the lung substance. In health the respiratory capacity of the lung is commensurate with the semi-circumference of the thorax. The diseased lung may be regarded as decreased in bulk, so far as function is concerned, by the amount of lung tissue involved, and it follows that the best mechanical conditions of respiration will be secured by reducing the thoracic cavity in proportion to the reduced bulk of lung. Natural processes tend to secure these conditions, but only lead to complete cicatrisation when the disease is of a very limited extent. We then find clinically a flattening of the chest wall, dislocation of adjacent organs or hypertrophy of the opposite lung, and anatomically a cicatrix, bands of fibrous tissue, a puckered lung surface and thickened pleura—all evidences of natural effort to fill up space originally occupied by healthy active lung tissue. Natural processes are unable to overcome the mechanical obstacles to complete cicatrisation when the disease involves more than a small maximum of lung tissue. ..... The obvious indication, then, is to aid the natural processes of repair by reducing the thoracic cavity, thereby relieving them of the work of strenuous, prolonged, and often inefficient cicatricial traction. In so far, then, as the inflammatory element in phthisis is concerned rest and relaxation of the inflamed tissues seem indicated and essential to the healing process. Comparative rest of the lung may be secured by keeping the patient at absolute rest day and night, but this system has obvious disadvantages, while it fails to fulfil the local indications of rest with relaxation. The English school aims at developing the latent resources of the lung so as to compensate for the loss of respiratory surface, while placing the patient under conditions inimical to the extension of the specific element of the disease and promoting general nutrition. In extreme cases where this object has been attained one finds an immense development of the base of the lung with extensive cavitation towards the apex. ..... Such cases suggest how much better it would have been if the compensatory hypertrophy had extended inwards instead of outwards so as to have invaded and occupied the excavated region." Dr. Tidey put his views to practical effect by strapping the lung, and he relates four cases all of which were greatly benefited by his method of rendering the lung functionally less active.

His results may be fairly claimed as a recommendation of the more radical procedure of attaining the same end by removing portions of rib to allow the fullest scope for those curative processes to which Dr. Tidey refers. Dr. Tidey concludes his paper with words which deserve to be well weighed: "I do not propose this method as a cure for phthisis, but as an essential element in the treatment of that disease directed against the inflammatory lesion, an element which will greatly enhance the value of specific and climatic treatment and without which those methods will be powerless to restore an extensively damaged lung to a condition of mechanical integrity. The latter essential is now habitually left to natural conservative processes which are inadequate to fulfil it when the lesion is extensive and only does so with difficulty when it is limited."

If the removal of portions of ribs by allowing contraction of the diseased portion of lung scotches, but does not absolutely strangle, the disease, it is worthy of consideration. Many men in the colonies who have gone out phthisical are going about at this day with damaged lungs, lungs with disease still in their apices, but innocuous and quiescent, and by promoting the formation of a case of

[2] Brit. Med Jour., March 21st, 189[illegible]

Digitized by Google

protecting tissue around the focus of the disease we may, perhaps, bring our patients into a similar state to those who go about their daily work in the colonies with disease in their lungs. But we shall, at any rate, do much to prevent absorption; we shall make the lung almost functionally inactive at the diseased spot and do something to prevent that most common and fatal occurrence—the lighting up of disease in the opposite lung. If we do this then I think the operation is justifiable—as justifiable as, if not more justifiable, than operation for cancer, where the hope of a few more months of life is enough to justify operations much more dangerous than the removal of portions of rib. Even as a palliative the procedure is worthy of careful consideration. And it has, at any rate, one recommendation—it does not interfere with any other method of treatment, medicinal, dietetic, hygienic, or climatic. As to which are the best cases for operation and at what stage of the disease it should be done further experience can alone determine. It should certainly be avoided in those cases which are running a rapid course; the more chronic the case the better suited to the operation will it be; moreover, it should be done early, without waiting for a cavity to form. I have watched several cases with the intention of operating as soon as excavation took place, but the onset of disease in the opposite lung and the rapid failure of the powers of the patient made me give up thoughts of doing it. This has occurred sufficiently often to make me say emphatically, Operate early. I would add to this recommendation that shrinking and flattening of the apex should be an indication for the operation, so as to give the fullest scope to the reparative process that shrinking indicates. At present the operation is applicable perhaps only to a minority of the cases—a minority which increasing experience may convert into a majority.

I am bold enough to think that the possibilities of this operation are not exhausted when the patient leaves the operation table. There seems to me no reason why at the apex of the lung the operation should not be the half-way-house to intra-pulmonary procedures. Let us assume that the operation does not cure and that a mass of tuberculous deposit or a cavity remains. The operation has been done; the falling in of the chest wall shows that the apex of the lung is contracted around the disease. The pleura will be adherent, and instead of an emphysematous layer teeming with blood-vessels intervening between the surgeon and the disease, the more or less solid, carnified, and altered lung substance, riddled here and there by bronchi and bronchioles but with blood-vessels small and contracted, has to be cut into. Not only will the disease be easier to locate and find but the attempt to reach and remove disease through such a covering will more resemble an operation in any other accessible part of the body. The possibilities in this direction may be such as to bring operations such as that of Dr. Lowson within the domain of the practicable, and with the aid of increasing experience we may emulate, if we cannot surpass, some of the triumphs of abdominal surgery. With the lung in a carnified state there should be no more, if as much, hæmorrhage in operating directly upon the lung than there is in the removal of the thyroid body, a structure with which carnified lung may for this purpose be not unfairly compared. We know how successful some of the operations upon abdominal viscera have been when done in two stages. It is evident that for pulmonary surgery to make any advance some fresh mode upon new lines is necessary; and it is with no other wish than to suggest a line of thought which has occurred to myself for the consideration of those of greater experience and ability that I venture to submit my views to the notice of my *confrères*.

Huddersfield.

EAST SUBURBAN MEDICAL PROTECTION SOCIETY.

The Plaistow branch of the East Suburban Medical Protection and Medico-Ethical Society held a well-attended meeting on Nov. 4th, Mr. Alfred E. Kennedy being in the chair. The following officers were elected:—Chairman: Mr. R. Buksh. Honorary treasurer: Dr. Edwin Hegan. Honorary secretary: Mr. Napier Jones. Representative on the Executive Council: Mr. F. E. Bromley. A sub-committee was appointed to collect evidence of the abuse of medical charities and provident institutions by persons resident in the district, and it was decided to compile a black list of bad payers of medical accounts. The next meeting will be held on Dec. 7th.

AGORAPHOBIA.[1]

BY J. HEADLEY NEALE, M.B. EDIN., M.R.C.P. LOND.,
PHYSICIAN TO THE LEICESTER INFIRMARY AND FEVER HOUSE.

AGORAPHOBIA (from the Greek, ἀγορά, a market place, and φόβος, fear), or the dread of an open space, is the symptomatic title given to a nervous affection which to my mind does not receive the attention which it merits from the profession at large. Typical cases were described by Benedikt in 1870, and in 1872 by Westphal, who, I believe, was the priest who christened the infant phenomenon by its present name. In 1884[2] Dr. Prosser White of Wigan gave a clinical account of a case under his care, one paragraph of which, touching upon treatment, is of so much significance that I shall take the liberty later of quoting it verbatim. Having been myself the victim of bad attacks of agoraphobia I followed suit with a paper describing my own experiences and symptoms, but just as I was about to despatch my MS. to the Editors of THE LANCET a somewhat sweeping letter appeared in that journal from a West-end physician, the gist of which was tantamount to saying that agoraphobia was all bosh and due to excess of wine and venery. As he was an old-established practitioner and I had been established as such only a year and a half, I think you will approve the discretion I showed in letting my paper remain where it was—viz., in my own keeping, where it still is. Unfortunately, after a lapse of thirteen years I have not been able to lay my hands upon it or I would have read it to you to-night. I am sure, however, that I have but little to add to what I then wrote, except that my personal experiences have since been confirmed by numbers of cases in my hospital and private practice, in the practices of my friends, and in individuals whom I have met with in a social but not professional capacity.

The "agoraphobic" is a much more common individual than you might be led to infer from the little which is said or written of him. You may recognise him as you walk behind him in the street, or, better still, if he finds his way into your consulting-room you will have occasion to ask him but few if any questions, so graphic and pathognomonic will be his statement of his symptoms. I am using the male pronoun for brevity, for be it understood that female agoraphobics exist in plenty, although the disorder is more common in males and is essentially one of adult life only. I have heard medical men pooh-pooh agoraphobia and vaguely hint at "male hysteria," as if some storm were raging in the sinus pocularis. It might rightly be described as a "gastro-neurosis," as I do not think I have met with a single case (my own included) in which there was not a previous history of long-standing dyspepsia.

If I describe my own case and the mode of onset of the first attack, I hope I shall not be thought guilty of obtrusive egoism—I do so merely for the purpose of illustration. So far from my agoraphobia being due to excess of wine and venery, it came on first when I was a student at Edinburgh, leading a strictly temperate and celibate life, working at high pressure and drawing largely upon my reserve forces. A day's programme of a summer session consisted of continuous work, rushing from theatre to theatre note-taking at lightning-like speed, demonstrations, ward work, &c., from 9 A.M. till 5.30 P.M., with only half an hour for a hasty lunch and a breath of fresh air. Then home to my lodgings; half an hour's sleep, followed by a hearty meal, and then the real work of the day began—rewriting and illustrating all my notes of the day, a certain amount of reading, and then out came the microscope, and it is no exaggeration to say that I constantly turned out the lamp to let the sun in, and was back at College by 9. My way home lay through Chalmers-street, a short, broad, lonely street ending in a *cul-de-sac* with a gate into the "Meadows," lined with grey, uncompromising-looking stone houses, the road so unused to traffic that the grass grew up between the stones. Walking briskly one evening down the slope I have my first attack; and it is the suddenness and unexpectedness of the first attack that is so alarming—a feeling that something dreadful is going to happen, that the end of all my strivings and longings has come. I stop; the heart seems seized in an iron grip. I feel as though I were going down into the

[1] A paper read before the Leicester Medical Society on Nov 4th, 1898.
[2] THE LANCET, Dec. 27th, 1884.

Digitized by Google

earth and the earth were coming up to meet me. There is no semblance of giddiness or faintness in these attacks, it is more a feeling of collapse as though one were being shut up like a crush hat or a Chinese lantern. I have a strong inclination to cry out and I feel that I must fall, so I lay hold of, and steady myself by, the palings. A deep heaving sigh, the breaking out of a cold sweat upon the forehead, and in less time than it takes to describe (a few seconds only) the attack has passed. Then quick as lightning comes the introspection and deception of the "agoraphobic." "Anyone looking out of his window will think I'm drunk," flashes through my mind, so I drop a book or stoop to tie a shoe-lace and then hurry homeward, restored by the consciousness that I am not dead.

This "fear of impending death" is the worst symptom of the disorder. Next in order comes that from which it takes its title—viz., the dread of an open space; this is called up by the sensation of vastness, infinity, and solitude. Then the inability to sit in the body of a church or a crowded meeting. All the time that I was an "agoraphobic" I attended church regularly with my family, but we always sat close to the door. There I was safe; but several times when attending public functions or when visiting I have been compelled to take a seat in the body of the church; an attack has come on, more especially when the organist, on any reference to lightnings or tempests has suddenly felt himself under an obligation to let fly every stop in the organ, and I have been obliged to hold on firmly to the back of the pew in front of me till the attack passed off. A sudden noise or a flash of bright sunlight upon a white pavement will induce an attack.

Now for a word as to the possibility of agoraphobia endangering life. Under ordinary circumstances the danger is *nil*, but under special conditions it may become serious. In the early days of my practice a journeyman carpenter with typical agoraphobia consulted me. I counselled him that if ever in the course of his work an attack came upon him to be sure and put himself in a place of safety till it had passed off, but that under ordinary conditions he could laugh at his complaint. I saw nothing of him for a long time, until one day I found him in the "accident ward" of our infirmary. He had been putting down the flooring in a new building, an attack had seized him, and he fell through the rafters, sustaining a compound fracture of the leg. And now I must relate how I very nearly lost my own life. I had gone to our county asylum one day in a professional capacity and on leaving, the late Dr. Higgins, the medical superintendent, who was an expert climber, pointed to a long ladder reaching to the roof, and said, "Come on up with me and I will show you one of the finest views to be had in Leicestershire." Up he went like a monkey and I followed. When within about a dozen rungs from the top a fit of agoraphobia came on. Had I once looked down I should not have been here to address you to-night. I looked up, counted the rungs of the ladder, called to him to give me his hand, laid hold of each rung with a strong muscular effort till I was able, with his assistance, to "land" upon the roof, where I nearly collapsed. It is needless to say that I have never been up a ladder since.

I have referred to the possibility of recognising the "agoraphobic" as he walks along the street. Apart from the coarser evidence of his suddenly pausing to lay hold of a paling or to place his hand upon a wall, he will hardly ever be without a stick or umbrella, which you will notice he will plant at each step at some distance from him, in order to increase his base line of support.

Now to discuss the selection by agoraphóbia of its victims. In my experience professional men suffer most, clergymen in particular, but I have known merchant princes, commercial travellers, middle-aged spinsters, and even young married women caught in its toils. I remember the case where a clergyman, the brother of a well-known doughty colonel (now deceased), holding a living in this county, suddenly collapsed and fell in a heap in the pulpit, which he never again entered. The last I heard of him was that he had gone on the Stock Exchange and was doing well. It seldom attacks poor people, but I had lately evidence of the exception to this rule. A strong, healthy-looking young married woman presented herself one day for admission to the infirmary. She staggered into the room and convulsively laid hold of the table, all the while swaying to and fro. Asked why she did this she said that she "always felt that she was sinking through the earth." I admitted her, and on my first visit to the ward I found her clutching the pillows as though her life depended on the effort. When remonstrated with for her foolish action she explained it by saying that she "felt as though she were going through the bed." I tried to reason her out of her silly fancies and told her plainly that if she continued to indulge in them she would finally find herself in the lunatic asylum. She discharged herself later, and has since become an inmate of that institution.

Under suitable conditions and treatment the prognosis of agoraphobia is favourable, but sometimes, especially in the case of weak, dyspeptic women, it runs through the course of deception, introspection, hypochondriasis, on to melancholia.

Treatment must be conducted primarily and essentially on a psychological basis. You must try to convince your patient that there is nothing in his condition inimical to life or which may not be overcome by strength of will. *Apropos* of this I will quote Dr. Prosser White's remarks upon his case: "These feelings and attacks may sometimes be avoided or lessened in severity by moral determination; deep concentration of thought will enable him to cross an open space, or certain places which otherwise induce these attacks of dread; companionship relieves the feeling of loneliness and fear. ..... The presence of a cart, even a stick or umbrella in the hand, gives a sense of confidence. ..... Cheerful and lively conversation with a congenial companion will always ward off the attacks." For the rest, the avoidance of overmental strain and of all excesses, a careful dietary, aids to digestion and tonics, will together contribute to a satisfactory issue and ensure the disappearance of this pathological "spook"—it being in reality but a phantom disorder.

Leicester.

A CASE OF PHTHISIS WITH PECULIAR CARDIAC PHYSICAL SIGNS.

By W. HALE WHITE, M.D. Lond.,
PHYSICIAN TO GUY'S HOSPITAL.

A MAN, aged forty-two years, a hall porter, was admitted into Guy's Hospital on August 17th, 1898. He had been a soldier. His family history and previous history are unimportant. He had been ill for about seven months, losing flesh and suffering from pain in the chest, cough, abundant expectoration, and sweating at night.

On admission he was pale, thin, and wasted. The left lung appeared normal, except for prolonged respiration at the apex in front and behind. The right chest was resonant down to the third intercostal space, and over this resonant area there were loud amphoric breathing and a bruit d'airain. Below the third interspace the front of the chest was absolutely dull, and loud bronchial breathing could be heard, together with consonating râles. Behind there was nothing noteworthy about the physical signs, except that there was evidence of a cavity at the apex of the lower lobe.

The heart.—On looking at the chest a beat exactly like the normal apex beat of the heart could be seen in the fifth right intercostal space just internal to the nipple. On placing the finger over this spot a beat was felt exactly like the normal cardiac apex beat. On auscultation over this spot the heart sounds were heard very much louder than at any other point in the chest. In the third and fourth right intercostal spaces a faint cardiac beat could be seen midway between the nipple and the sternum. In a bad light no impulse of the heart could be seen in the normal position internal to the left nipple, nor, indeed, could any cardiac beat be detected on the left side, although with the same amount of light the beat on the right side was easily visible. In a bright light a faint cardiac impulse could be seen in the fifth left intercostal space just internal to the nipple. This beat could be felt and the cardiac sounds could be heard over it, but the tactile impulse was very poor compared with that below the right nipple, and the sounds over the left impulse were not nearly so loud as they were over the right.

Cardiac dulness.—The resonance of the left lung extended over the normal cardiac dulness. On the right side the cardiac dulness could not be determined because of the consolidation of the lung.

The patient developed pleurisy and suddenly and unexpectedly died on Sept. 2nd. The physical signs remained unaltered during the time he was under observation.

When I saw this man it seemed to me that the only way to satisfactorily account for his physical signs was to believe that pleuritic adhesions and contraction of fibroid tissue in

Digitized by Google

the right lung had dragged the heart over to the right, so that the apex or some other part of the heart was causing an impulse in the fifth right intercostal space. I thought that the very much fainter impulse on the left side might be due to the normal attachments of the pericardium. The explanation here suggested would also account for the loudness of the sounds near the right nipple. The only objection to this view was that there was not much falling-in of the right side of the chest.

The post-mortem examination, however, showed that the heart was in its natural position. It lay in its usual position in the pericardium and its right side was naturally adjacent to the right lung. The whole of the upper lobe of the right lung was converted into a large cavity, the largest, I think, I have ever seen, while the middle and lower lobes were completely solid, except that the lower lobe had some small cavities in the upper part at the back. This condition of things readily explained why the cardiac sounds were heard so loudly on the right side, for the solid lung would have conducted them well and the adjacent large cavity acting as a resonator would have intensified them. But there was no explanation why the impulse should have been so well marked both to sight and touch in the fifth right intercostal space. I know of no reason why solid lung should conduct it to this spot; indeed, as a rule, solid lung does not cause the impulse to be felt in abnormal positions, for this transference of impulse is not a feature of lobar pneumonia.

I have thought this case worthy to be put on record because it seemed to me to show that we must not assume that when the heart's impulse is seen and felt far on to the right side of the chest the organ is necessarily dragged or pushed over or altered in size.

Harley-street, W.

LAPAROTOMY FOR INTUSSUSCEPTION.

BY R. W. MURRAY, F.R.C.S. ENG.,
SURGEON TO THE LIVERPOOL INFIRMARY FOR CHILDREN.

THE treatment of intussusception in young children has of recent years been frequently dealt with in the columns of THE LANCET and it would appear that there is an ever-increasing tendency on the part of surgeons to discard the uncertain and somewhat dangerous method of attempting reduction by means of rectal injections and to practise earlier the more certain method of abdominal section. As to the uncertainty of reduction by rectal injection Dr. Holme Wiggin[1] in his most interesting and instructive review of the treatment of intussusception, showed that the failures to effect reduction after rectal injections amount to 75 per cent., and, curiously enough, the same proportion of failures holds good in the cases of this nature so treated at the Liverpool Infirmary for Children during the last ten years. Of 16 cases of intussusception under treatment during that period rectal injections were tried in 12 and were successful in 4 only. In 2 of these 12 cases laparotomy was subsequently performed and the invaginated portion of the bowel reduced, and the patients recovered. As to the dangers of rectal injections Mr. J. D. Mortimer[2] has demonstrated that if the funnel of the injecting tube be raised to a greater height than 3 ft. from the level of the child's body there is a very real danger of rupturing the young and inflamed gut.

My personal experience of laparotomy for intussusception is limited to 6 cases. In one case, that of a boy aged four years, the intussusception was of a chronic nature, and after several unsuccessful attempts at reduction had been made by means of rectal injections of water the abdomen was opened and the intussusception, which was of the ileo-cæcal variety, reduced. The child completely recovered. In the other 5 cases the patients were all under twelve months of age and much collapsed at the time of operation. In one instance the intussusception had existed for four days without treatment. Laparotomy was performed, but the reduction was a matter of considerable difficulty, the peritoneal coat of the bowel tearing. The child died twelve hours later. In a second case I first saw the child on the fifth day of the illness. Rectal injections had been previously tried. I opened the abdomen at once, but the intussusception could not be reduced; it was excised and the patient died. In a third case the symptoms of intussusception had existed for twenty-four hours. Primary laparotomy was performed. The reduction was difficult, the peritoneal coat of the bowel tearing. This child also died. In a fourth case I saw the patient twenty-four hours after the onset of the symptoms and the invagination could then be felt from the rectum. Reduction by means of water was attempted, which, however, was not successful, and on the following day I opened the abdomen and the bowel was so tightly strangulated that reduction of the invagination was impossible. It was therefore excised and the child died shortly afterwards. In this instance I believe the bowel became strangulated very early, and I doubt whether if primary laparotomy had been performed we could have saved the patient. The fifth case was successful and therefore presumably being more interesting I will relate it a little more fully.

A female infant, aged six months, was seen in the out-patient department of the Liverpool Infirmary for Children by my colleague, Dr. Percy Marsh, on the afternoon of May 27th, 1898, and was at once admitted. The patient was a well-nourished breast-fed infant and had been quite well up to 11.30 P.M. of May 26th, when she cried apparently from pain and was restless and vomited. The next morning the child was seriously ill and blood and mucus were passed per rectum. I saw her shortly after her admission and the collapse was so great that when I entered the ward oxygen was being administered. The intussusception could be easily felt through the abdominal wall and occupied the position of the transverse colon. No tumour could be felt from the rectum, but on withdrawing the finger blood and mucus escaped. It struck us as being extremely doubtful whether we could save the child, and if anything was to be done it must be done at once and done quickly. A little chloroform was given, the abdomen opened in the middle line, and the intussusception, which was of the ileo-cæcal variety and about 6in. in length, was found, brought to the surface, and reduced. The reduction was easy up to the final piece, which offered some resistance. The portion of the gut which had been invaginated was washed with warm boric lotion and returned into the abdomen. The abdominal wound was completely closed. The general condition of the child afterwards appeared to be much the same as it was before the operation, but the next morning there was a marked change for the better. The subsequent convalescence was uneventful and the patient completely recovered. In this particular instance, though the case was brought early for treatment, I feel sure we did the right thing in at once performing laparotomy, for although the intussusception was reduced with the fingers without much difficulty, still I doubt very much whether rectal injections would have been equally successful, and the condition of the child would not admit of primary failure. In performing the operation I was so admirably assisted by my house surgeon and the nurses that the time occupied was exceptionally short, and as, other things being equal, in cases of this nature rapidity makes for success I may perhaps be excused for mentioning the following details. Dr. Percy Marsh, who was present at the operation, told me afterwards that he had timed it and that the abdomen was opened and the intussusception reduced in four minutes, the bowel returned and the abdominal wound sewn up in three and a half minutes, so that the whole operation lasted only seven and a half minutes.

If, then, it is a fact that the chances against the successful reduction of an intussusception by means of rectal injections are as three to one, surely it would be well when circumstances permit of it to perform primary laparotomy, for it is a far more certain method, and the record of published cases of laparotomy for intussusception during the last five years is very encouraging, and as an operation it is not necessarily more dangerous than attempted reduction by means of rectal injections.

It is, I believe, impossible to say in any individual case whether the intussusception will be easily reduced or not, and if after opening the abdomen the invagination is easily reduced then the operation may be completed in a few minutes. If, on the other hand, the reduction is difficult or impossible the child is obviously in a better condition to stand a severe operation than if he had already been subjected to a rectal injection.

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

DIPHTHERIA BACILLI IN THE URINE.

BY CAPTAIN FREDERICK SMITH, R.A.M.C., D.P.H. DURH.,
LATE OF THE BACTERIOLOGICAL DEPARTMENT OF THE ARMY MEDICAL SCHOOL.

THE following notes were made some ten months ago, but were not published as it was hoped that a more complete inquiry into the subject could first be carried out. The exigencies of active military service, however, prevented anything further being done, and as there is no immediate prospect of an opportunity to resume the work it is thought desirable to put forward this instalment of the subject.

A guinea-pig which had been some days before injected with live broth culture of diphtheria bacilli was noticed to be passing hæmorrhagic urine, and the idea at once suggested itself—if blood, why not bacilli? The animal was killed and opened aseptically and the bladder was exposed. The viscus was touched with a heated glass rod and pierced at the sterilised spot by a glass pipette. Bloody urine thus obtained in the pipette was run over the surface of coagulated serum in a Petrie dish. After incubation a copious growth of typical Klebs-Löffler bacilli was the result.

A second guinea-pig was injected with a living culture. The animal was killed five hours later and the urine was obtained aseptically in the manner above detailed. The urine was normal in appearance, but a plentiful growth of diphtheria bacilli on serum was obtained.

The result in the case of the second guinea-pig is somewhat surprising considering the short time which elapsed between injection and death. These facts go to prove that, in the guinea-pig at any rate, bacilli in the blood-stream are some of them eliminated alive through the kidneys. It does not follow, of course, that diphtheria bacilli are passed alive through the kidney of a human being suffering from diphtherial disease. For all that, the results obtained suggest that, at least in hæmorrhagic diphtheria, bacilli will be found in the urine. It may further be anticipated that in all cases in which the bacillus (whether in small or large numbers) escapes into the blood-stream it will be present in the urine. It may be predicted even that in order to prove the presence of the bacillus in the blood search for it will be made in the urine in future. The practical bearing of this question is important from the public health point of view. If the urine of diphtheria patients is liable to contain the bacillus, the urine and fæces (for the solid excreta are almost invariably mixed with more or less urine) will have to be disinfected just as rigorously as those of patients suffering from enteric fever. Those hygienists who have so strenuously maintained that there is a connexion between general insanitation, middens, &c., and diphtheria will have a new fact to strengthen their argument.

Sherbro, Sierra Leone.

IDIOSYNCRASY TOWARDS POTASSIUM CHLORATE?

BY WILLIAM ROBERT CULLING, L.R.C.P. EDIN., L.S.A.

Is this a case of idiosyncrasy towards potassium chlorate, or how are the symytoms to be interpreted?

A man, aged about fifty years, a painter, consulted me on June 28th, 1898, for a general dermatitis, especially on the legs. I prescribed liquor arsenicalis, 3 minims; potassium chlorate, 10 grains; tincture of hyoscyamus, 15 minims, twice daily in a wineglassful of water. The first dose made him feel cold, and as he persevered he noticed after each dose that the time he felt cold was evidently longer; however, as he improved he stuck to his medicine pretty regularly until Sept. 16th, when he began to think that the remedy was nearly as bad as the disease. His description to me of his trouble to take his medicine was: "You ordered me to take it after breakfast and after supper in a wineglass of water." "Quite right," I remarked. "Well," he said, "I tell you what I do. After breakfast I get my wife to make up the kitchen fire. I then drink off my dose, button up my coat as you see (an ordinary frock coat), get my overcoat, put it on and button it up, and there I sit till dinner time, teeth chattering—in fact, shivering and shaking all over. When I get my dinner I feel better." "Breakfast at 8 A.M. and dinner at 1 P.M.?" I remarked. "As near as possible," he replied, "and then at night I take the medicine directly after supper, get into bed and cover myself up just as I should in the midst of winter, going through the same as I described after my morning dose." These are as nearly as possible his own words. Now he wished to be let off his performance, so under the circumstances I advised him to discontinue his mixture for a week at any rate to see if the external applications would not complete a cure.

Jermyn-street, S.W.

NOTE ON A CASE OF PERSISTENCE OF HYMEN; RETAINED MISCARRIAGE.

BY W. HARPER WIGHAM, M.B. DURH., M.R.C.S. ENG.

IN THE LANCET of Nov. 12th were published the notes of Dr. N. Cullinan on a case of persistence of the hymen into the second stage of labour, in connexion with which the following case may be worth recording.

I was consulted—I purposely refrain from giving dates—by a young woman who complained of being "irregular" and of having "the whites." Without local examination, of course, but after an examination of the heart and, what was as important, an inspection of the breasts, which gave no indication of pregnancy, I prescribed an iron tonic for internal use and an astringent lotion for local application. Going away for a holiday I did not see the patient again for nearly three weeks, but on her calling again in my absence my prescriptions had been once repeated. I saw her in consultation on my return with her mother who accompanied her. I continued the treatment, at the same time suggesting a local examination if the symptoms did not abate. A few days later I was requested to make the examination at the parents' house in the presence of the mother. On visual examination the labia were found to be covered with a discharge of a very unpleasant and sickly odour. On carefully attempting to make a digital vaginal examination I found an obstruction—an extremely tough and dense hymen—existing, with a great convexity downwards and outwards and with a feeling of resistance, as if something solid existed beyond. There was found to be one small opening in the membrane in the anterior third just below the pubes through which an attempt was made to insinuate the forefinger. The patient cried out that she was being very much hurt; but being satisfied in my own mind that there was something beyond which required investigation, with the consent of the patient and her mother I administered chloroform and then continued my examination. Having enlarged the opening in the membrane by forcing my forefinger through I discovered a hard mass behind and on withdrawing my finger a disagreeable putrid odour clung to it. I deemed it necessary to break down the hymen in its entirety, upon which there was a fair amount of hæmorrhage. Proceeding I discovered that the mass above was none other than a fœtus of about the fourth month with cord and placenta all lying together in a globular dilatation of the upper part of the vagina. Having got them away I prolonged my examination upwards, only to find that the os was closed and apparently normal and that the uterus was well contracted down. From the above facts with regard to the uterus and from the putrefaction of the fœtus the condition had apparently existed over a month at least.

There are in this case, then, the fact of impregnation taking place with non-rupture of the hymen, the more extraordinary one of its persistence on the occurrence of abortion, and the further one that the patient did her ordinary work under the conditions which are recorded above.

A Mirror OF HOSPITAL PRACTICE, BRITISH AND FOREIGN.

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv. Procemium.

WESTMINSTER HOSPITAL.

A CASE OF COMPOUND SEPARATION OF THE LOWER EPIPHYSIS OF BOTH RADIUS AND ULNA, FOLLOWED BY ACUTE TETANUS, TREATED WITH TETANUS ANTITOXIN AND IRRIGATION OF THE WOUND WITH OXYGEN GAS WITHOUT RELIEF.

(Under the care of Mr. CHARLES STONHAM.)

ALTHOUGH the injury inflicted on the radius and ulna in the following case is of great rarity, yet the chief interest in it is associated with the use of tetanus antitoxin. Numerous cases of tetanus have been recorded in which the administration of this substance has been followed by recovery, but it is very far from being certain that tetanus antitoxin has much influence on the result. In a fair proportion of cases tetanus ends in recovery when only sedatives have been employed, and this is especially true of those cases in which the onset of the symptoms is long delayed. In acute cases all forms of treatment seem equally useless, and it cannot be said that any more favourable results are obtained by the use of the antitoxin than by other remedies. It is possible that large doses might be successful, for the antitoxin seems rarely to give rise to any unfavourable symptoms. The failure of the substance in Mr. Stonham's case is a greater reason for the publication of the case than if the patient had recovered. In all cases in which antitoxins have been employed it is desirable to record the source whence it has been procured. For the notes of the case we are indebted to Mr. E. Percy Paton, surgical registrar.

A boy, aged fourteen years, a plumber's mate, was admitted into Westminster Hospital on Dec. 11th, 1896, having just fallen 20 ft. from a ladder. On examination there was found a wound, between 2 in. and 3 in. long, extending transversely across the right forearm just above the wrist-joint on the flexor aspect. The wound was begrimed with dirt and through it protruded the lower ends of the diaphyses of the radius and ulna. He was at once anæsthetised and the wound was cleaned, the fractures were reduced, and the wound was closed by the house surgeon, the arm being put up on a splint. All went well for the next day or two except that the temperature rose somewhat, and the stitches had to be removed to let out some pus on Dec. 13th, and treatment by an arm-bath was commenced. He seemed gradually to improve, the temperature steadily falling. On the 16th the patient complained of a little pain in the right shoulder, but nothing to account for it was found, and it seemed to be due merely to fatigue from holding the arm in the arm bath. At 6 A.M. on the 18th he was suddenly seized with a kind of fit; there was general rigidity, especially of the muscles of the neck and the muscles of the back. The head was drawn backwards and the jaws also were tightly clenched. The severity of the pain made him cry out. At 11.45 A.M. the stiffness of the jaw was rather better, but the risus sardonicus was slightly marked and occasionally the muscles of the neck were distinctly stiff and the back was strongly arched, but no rigidity was noticeable in the limbs. The condition of the wound was unaltered from the day before and the temperature was rather lower. At 12 noon he was given 15 gr. of chloral hydrate and of bromide of potassium. At 2 P.M. chloroform was given and the wound was thoroughly cleaned and irrigated with oxygen gas. On recovery from the anæsthesia the general rigidity of the trunk and head returned, but the limbs were still very little affected. At 4 P.M. he was given croton oil (½ m.), which acted well, and at 5.30 the chloral and bromide mixture was repeated. At 10 P.M. 15 c.c. of the tetanus antitoxin, obtained from the Institute of Preventive Medicine, were injected; it was not followed by any immediate results, but at 2 A.M. on the 19th it was noticed that he opened his mouth widely several times, and a little later the stiffness of the back and neck seemed much less; but by 3 A.M. these symptoms had all returned. At 4 A.M. 8 c.c. of antitoxin were injected and at 6 A.M. the chloral and bromide mixture was repeated, but without any signs of improvement, though there were no violent spasms. At 8.50 A.M. he had a bad spasm, which lasted about twenty minutes, and in which all the limbs moved. It was followed almost at once by a second spasm which only lasted two minutes. In both there were very marked opisthotonos and trismus. Immediately afterwards the wound was dressed and again irrigated with oxygen. At 10.30 A.M. 12 c.c. of antitoxin were injected and at 12 noon the chloral and bromide draught was repeated, but at 2.30 P.M. he was seized with a more violent spasm, became very blue, and died.

Necropsy.—The wound showed extensive laceration of the soft parts surrounding the ends of the radius and ulna; the epiphyses of both bones were separated; the median nerve had been torn across and its upper end was bulbous. The brain weighed 56 oz. and seemed somewhat flabby, but otherwise neither it nor the spinal cord showed any abnormal naked-eye appearances. There was a small amount of greenish pus in the left middle-ear. Nothing abnormal was discovered in any other organ or part of the body. An examination was also made during life of the pus from the wound, which was found to contain the tetanus bacillus. This was further demonstrated by cultivation, when specimens were obtained of the bacillus showing typical spore development.

Remarks by Mr. PATON.—This case appears to be worth recording, in the first place because of the infrequency of separation of the lower epiphyses of the radius and ulna, but more especially as a case in which the tetanus which supervened was treated with tetanus antitoxin, and this without any relief to the symptoms. The antitoxin treatment of tetanus is still on its trial, so that it seems advisable that as far as possible all cases, both successful and unsuccessful, should be recorded. It will no doubt be said by the advocates of the treatment that in such an acute case as this, in which the disease ran its course in about thirty-six hours from commencement to termination, no treatment is likely to be of any avail. On the other hand, it may be said with equal truth that the less acute the case is the more tendency there is for a spontaneous cure to result from the mere resisting power of the patient and thus a fictitious appearance of success may be given to any treatment, such as that by antitoxin, which may have been tried, so that it may be argued with some reasonableness that the acuter the case the better test it will be of any form of treatment which professes to cut short the disease process. In the case of which the notes are given above, as far as could be seen, no relief to any of the symptoms resulted from the injections, while, on the other hand, they appeared to have no deleterious effect.

ROYAL INFIRMARY, NEWCASTLE-UPON-TYNE.

A CASE OF CARBOLIC ACID POISONING TREATED BY VENESECTION AND INJECTION OF SALINE FLUID; RAPID RECOVERY.

(Under the care of Dr. T. OLIVER.)

APART from the severe local effects of carbolic acid, which of themselves may cause death, the fatal result is due to the action of the poison after absorption. The attempt to remove this absorbed carbolic acid by injecting saline fluids into the vascular system is well deserving of extended trial, for the added fluid is in great part rapidly excreted by the kidney and carries no small portion of the poison away with it. The method employed in the case recorded below to remove still more of the drug by performing venesection is ingenious, but we do not think that it is likely to prove of much value. In Dr. Oliver's case 8 oz. of blood were removed; now this quantity is only about 5 or 6 per cent. of the total quantity of blood in the body, and therefore the withdrawal of this amount of blood would only mean the withdrawal from the body of the corresponding percentage of the poison. Of course the removal of even 5 per cent. of the poison absorbed will assist the recovery, but we do not feel inclined to look for so much benefit from it as we should

Digitized by Google

expect from the method of saline injection. In considering that 8 oz. of blood would only equal 5 or 6 per cent. of the total weight of blood in the body we have taken the usual estimate that the blood forms one-thirteenth of the body weight, and we may fairly suppose that the patient weighed between 8 st. and 10 st.

An unmarried woman, aged twenty-one years, was admitted to the infirmary in a state of coma due to carbolic acid intoxication. She was received by the house physician, Dr. Rowell, to whom is due the merit of successful treatment of the patient. In the article on Carbolic Acid Poisoning in Allbutt's "System of Medicine," vol. ii., Dr. Oliver draws attention to the desirability once carbolic acid in any quantity has been absorbed into the blood of washing out the poison by means of saline fluid, but in the present instance venesection was practised as well. It appears that about three-quarters of an hour before her admission into the infirmary the patient, who had had a quarrel with her father, swallowed seven drachms of ordinary commercial carbolic acid. When Dr. Rowell saw her she was comatose and collapsed; there was no corneal reflex; the pupils were contracted; she was cyanosed; respiration was slow and shallow, and if the lower jaw was not supported it fell back and stopped the breathing. The pulse, at first of medium rate and volume, became flickering and was with difficulty counted. The breath smelt strongly of carbolic acid. The lips, mouth, and fauces were corroded and blistered. A soft indiarubber stomach tube was passed with difficulty down the œsophagus and the stomach was freely washed out with warm water containing some sulphate of soda. While this was being done the internal saphenous vein of the left leg was opened and eight ounces of blood were removed Four pints of a normal saline solution at a temperature of 110° F. were then injected into the vein; $\frac{1}{10}$ gr. of sulphate of atropia was given hypodermically to stimulate her respiratory centre. Half a pint of milk beaten up with two eggs, to which was added one minim of croton oil, was passed down the stomach tube. By degrees the patient, who at first seemed moribund, began to come round, her pulse gradually improved, and the respiratory movements became stronger. In a few hours she had rallied sufficiently to recognise those around her. Glycerine in drachm doses was given frequently to allay the burning sensation in her throat and œsophagus. On the following day when seen by Dr. Oliver she seemed remarkably well and the pulse was good. There was still pain on pressing the epigastrium. For three days the urine was dark green in colour; it contained phosphates but never albumin. The wound made in the leg healed kindly and recovery generally was rapid and complete.

Remarks by Dr. OLIVER.—Once a poison like carbolic acid has got into the blood washing out of the stomach is not enough. The rational treatment is, in addition, to transfuse, or to do as was done in this case, bleed and transfuse.

Medical Societies.

MEDICAL SOCIETY OF LONDON.

Gastro-jejunostomy.—Anomalous Murmur.—Aneurysm of the Common Carotid Artery.—Diabetes Insipidus.—Sarcoma treated by Coley's Fluid. — Hepatoptosis. — Multiple Patellæ.—Genu Retrorsum.—Multiple Fibromata.

A CLINICAL meeting of this society was held on Nov. 14th, the President, Mr. EDMUND OWEN, being in the chair.

The PRESIDENT showed a case of Gastro-enterostomy performed for Inoperable Disease of the Pylorus. The patient, a man, aged thirty-one years, for a twelvemonth had discomfort in the pyloric region with vomiting after meals. He had lost his appetite and could neither work nor sleep; he was greatly emaciated. The stomach was much dilated. On July 18th abdominal section was performed; the pylorus was obscured and fixed by a hard mass surrounded by enlarged lymphatic glands. A communication was made between the front of the stomach and an adjacent piece of jejunum by means of a Murphy's button. The man can now eat and drink anything; he has lost his dyspepsia and has become almost robust. Nothing has yet been seen of the button, but, wherever it is, it is doing no harm.—Mr. BATTLE asked what size of button was used, also the exact position of communication with the stomach. He also asked how soon after operation food was given by the mouth and as to the duration of the previous illness. He inquired what was the amount of the glandular enlargement. He gathered that the President believed it to be a case of malignant disease of the pylorus, in which case, of course, the prognosis was necessarily unsatisfactory. He himself had operated on a man, aged twenty-eight years, last year for pyloric obstruction of some duration though the symptoms were acute. Although the duration of the malady was but short he found extensive growths in the glands and multiple growths on the peritoneum. The patient did extremely well after the operation but died six weeks later from malignant disease of the pleura.—The PRESIDENT, in reply, said the lumen of the stalk of the button was of about the size of the top of his little finger and when it sloughed away would leave an aperture of about the size of a shilling, which he feared would go on contracting. The disease in his case had lasted about twelve months. He made his opening into the stomach in the anterior part low down quite clear of any vessels. He had fixed a piece of jejunum to the front of the stomach, where it was in apposition. He said the question had been raised as to the advisability of making the opening in the anterior part of the stomach on account of the risk of a kink, but his experience had not suggested anything of the kind. He began to give the patient home-made beef jelly on the day after the operation. He thought it was a malignant growth and the prognosis was therefore decidedly bad.

Dr. HECTOR MACKENZIE showed a case of Vascular Murmur of obscure origin, audible at the base of the right lung. The patient was a man, aged forty-one years, who had been under treatment for recurrent hæmoptysis at the Brompton Hospital during the last four years. Throughout the first period of attendance, from August, 1894, to May, 1895, there were five attacks of hæmoptysis, which were all slight, and the only abnormal physical signs then observed were diminished resonance, bronchial breathing, and pectoriloquy at the right apex. The patient kept fairly well until August, 1897, when hæmoptysis recurred and he again presented himself at the hospital. He had a cough with yellow expectoration and complained of night sweats and loss of appetite. The physical signs at the right apex were the same as before with the addition of crepitations, but it was now discovered that at the base of the right lung a very peculiar vascular murmur was present. The murmur was loud and blowing and occupied nearly the whole period of the cardiac cycle. In character it very closely resembled the murmur produced by a communication between an artery and a vein, such as sometimes occurred in cases of aneurysm. The murmur increased in intensity with inspiration, but was not obviously altered when the patient held his breath either in inspiration or expiration. The position of maximum intensity was situated over the seventh, eighth, and ninth ribs in the posterior axillary line, on either side of which the murmur was distinctly audible for two or three inches. There were no other abnormal physical signs at the right base, no dulness, no phlsation, no alteration of breath or voice sounds. Since it was first noticed the murmur had not altered either in character or situation. During the last year there had been numerous slight attacks of hæmoptysis, but during the intervals the patient had been fairly well and able to continue his work as a draughtsman. There had been no change in the physical signs at the right apex. Dr. Mackenzie was unable to offer any explanation of the cause of the vascular murmur. It was possible that it might be due to a vascular growth in the lung. It was unlikely from the situation that it was produced by an aneurysm. The fact that the patient had pulmonary tubercle was sufficient explanation of the attacks of hæmoptysis, which probably was quite unconnected with the condition which gave rise to the murmur.—Dr. MAGUIRE said the only condition he could suggest as the cause of the murmur was an angioma of the liver. The murmur resembled that heard over the jugular vein in anæmia and was increased in intensity during inspiration. Moreover, the upper part of the liver seemed to be somewhat irregular behind on percussion. He admitted that angiomas of the liver were usually small and were often embedded in the substance of the organ, but he had seen one as large as a duck's egg which would suffice to cause a similar murmur.—The PRESIDENT asked whether there were any "mother's marks" which might suggest the murmur being due to a nævoid formation.—Dr. CALEY suggested that the murmur might be

Digitized by Google

generated in connexion with the vena cava at its passage through the diaphragm. It was remarkable what a difference there was during inspiration and this he thought was consistent with a relative stenosis of the vena cava in that situation.—Dr. MACKENZIE, in reply, said there were no mother's marks and he had not been able to make out any irregularity of the upper border of the liver as stated by Dr. Maguire.

Dr. SEYMOUR TAYLOR showed a case of Aneurysm of the Right Common Carotid Artery occurring in a man, aged thirty-five years. The aneurysm was of the size of a turkey's egg, extending from the left sterno-clavicular joint to the level of the hyoid bone. It caused no pain or distress and the vocal cords were not paralysed. The symptoms had developed after the ligature of both superficial femoral arteries for popliteal aneurysm. There were no signs of aortic aneurysm.—The PRESIDENT observed that if one asked a student the causation of arteritis he would certainly incriminate syphilis, but personally he was not so sure that it was an important factor in the etiology of arteritis. He recalled the observation of an officer in the Indian Medical Service who commented on the fact that while syphilis was prevalent in India aneurysm was very rare. It was an interesting fact that this patient had at the same time two popliteal aneurysms and a swelling of the carotid at its bifurcation. He himself would not advise proximal ligature in such a case and suggested that it might be better to try the effects of distal ligature followed by the injection of a coagulating fluid into the sac.—Dr. TAYLOR, in reply, agreed with the last suggestion, adding that of course ligature of the common carotid presented two great risks, viz., sepsis and the danger of hemiplegia as the result of interference with the cerebral circulation. If the obstruction to the circulation could be done gradually it was quite possible that a collateral circulation would be established. He had not attempted any treatment so far, but as Mr. W. G. Spencer described the case as one of syphilitic arteritis he would now try the effect of anti-syphilitic medication.

Dr. WILFRED HADLEY showed a case of Diabetes Insipidus in a woman. There was no family history bearing on the case. She had purulent otorrhœa when twenty-one years of age. She had had thirst and polyuria for over two years and attacks of giddiness with misty vision, and she had lost 2 st. in weight in the last two years. There were no other signs of disease of the nervous system. The average amount of urine passed per diem was 216 oz. The specific gravity was low, but the total daily nitrogen was slightly above the average.—Dr. S. TAYLOR said that on first seeing the patient he thought it was a case of myxœdema. Her face was swollen and bloated and there was a tendency to the red patch on the cheeks. Her voice was of the typical leathery intonation, and he thought if the case was watched that symptoms would develop showing that the case was one of typical myxœdema. It was just on the borderland of the kind referred to by Dr. Ord in his last Bradshaw Lecture.—Dr. MAGUIRE said the pathology of these cases was extremely obscure. It was difficult to decide the usual state of the blood tension and neither feeling the pulse nor the sphygmometer gave trustworthy information. He had recently tried to use a sphygmometer but with indifferent success, but if in the future they could obtain the means of telling more accurately the state of the blood tension in general they would be enabled to get at a pulse tension which might be characteristic of the disease as a whole. In this case it seemed to be high.—Mr. BATTLE said that when he was house physician at St. Thomas's Hospital a patient was admitted, unconscious, under the care of Dr. Payne, passing many pints of urine in the day, in whom post mortem a gumma was found in the floor of the fourth ventricle. He asked if there was any specific history in Dr. Hadley's case.—Dr. HADLEY, in reply, said that he had noticed the myxœdematous appearance and he had, moreover, noticed the same thing in other cases of the kind. He thought the symptoms might be due to the enormous amount of fluid drunk by the patient, which being consumed quickly might determine heightened arterial tension, which in its turn might determine the bloated appearance. Her appearance was that of a person who drank. The voice was worse when she had had nothing to drink for some time. He thought the peculiarity was due to the sticky dryness of the fauces. The blood tension appeared to him to be medium. She had always a faint but unmistakeable trace of albumin in the urine and there was always a doubt in these cases whether they might not be abnormal cases of commencing granular kidney. The patient was a single woman who had never had a child or a miscarriage and there was nothing to suggest a specific history. He had therefore not administered iodide of potassium. Bernard had shown that polyuria might be produced by puncture of the fourth ventricle at a spot higher than the spot puncture whereof gave rise to glycosuria.

Mr. BATTLE showed a man who had already been exhibited before the society while under Treatment for Sarcoma by Coley's Fluid. He then presented a large tumour under the right clavicle extending down the chest, another above the clavicle extending into the posterior triangle of the neck, and others over the sternum, &c., with numerous diseased glands in the axilla. He was treated by half-minim doses of Coley's fluid injected into the arm, gradually increased to one minim. The total quantity did not exceed twenty-four minims. The treatment was carried on for three months, ceasing in May last. His progress had been very satisfactory, and actually there was no trace of the tumours. Microscopical examination of portions of the growths from the sternum, &c., had shown the growth to be composed of spindle cells with some large cells.—The PRESIDENT said the diagnosis of sarcoma did not appear to be certain, and he thought the examination of specimens removed from the living subject apt to mislead. If it were a sarcoma why were the glands in the axilla enlarged? It would be very unlikely that a sarcoma of the breast or in its neighbourhood would infect the axillary glands. He suggested that it might be a case of granuloma of syphilitic or tuberculous origin. He asked whether the patient had had syphilis.—Mr. MANSELL MOULLIN congratulated Mr. Battle on having shown the first authentic case of dispersion of tumour by Coley's fluid in England. He himself had seen the tumour and the various secondary growths, and he had also seen the microscopical sections and he could not conceive that the tumour was anything but sarcoma. He said there was a great tendency to doubt Coley and Coley's statements. Last year he himself had brought forward two cases before the society in which the tumours had disappeared under this treatment. They were intra-abdominal tumours, so that he was not in a position to affirm positively that they were sarcomatous. He had also published a third case of a tumour growing in the iliac region which also did not admit of conclusive proof, but it completely disappeared. He admitted that none of his cases could be proved to be sarcomatous, but they were certainly not inflammatory and they were not gummatous and they disappeared under treatment by Coley's fluid. Mr. Battle's case was the first in which there had been a thorough microscopical examination. He said he had seen a good deal of Dr. Coley and he believed everything that gentleman stated. Coley had published a large series of cases of spindle-celled sarcoma, every one of which had been influenced by his fluid, though all had not been cured. He believed, however, that all the spindle-celled cases had been favourably influenced and in a large proportion of the cases the tumours had disappeared completely and in some there had been no recurrence for upwards of seven years. These cases were authenticated by microscopical examination by well-known American observers. He believed that in Coley's fluid they had a remedy for spindle-celled sarcoma, not perhaps an ideal remedy, because it was somewhat dangerous and it did not succeed in all cases, but they were evidently on the right track. Recurrence sometimes took place, but so it did sometimes after operation, yet he had never heard operation decried because it did not afford a guarantee against recurrence. Therefore, if recurrence did take place with the fluid the latter was not in a worse position than operation.—Dr. MAGUIRE related a case at St. Mary's Hospital sent to him by Mr. J. E. Lane, who had amputated through the upper third of the thigh for sarcoma. The patient was spitting blood and there was evidence of recurrence in the stump and probably also in the stomach. It was an absolutely hopeless case, but with the patient's consent he tried Coley's fluid, injecting it directly into the veins of the arm so as to obtain a constitutional effect. He injected first 3 and then 5 minims for ten days every other day without the slightest ill effect and with relief to some of the symptoms. The patient died and post mortem it was shown that the case was necessarily quite hopeless, the lungs being riddled with sarcomatous nodules.—The PRESIDENT said that while they did not doubt Coley in the

Digitized by Google

least, that did not prevent a feeling of scepticism as to the diagnosis of sarcoma in these cases. It was good that there should be some enthusiasts. One case which was treated for malignant disease of the end of the femur by Coley's fluid eventually found its way into another hospital, where the patient underwent excision for tuberculous hip-joint disease. If that case had got well under Coley's fluid what a splendid triumph it would have been. He admitted that he was a sceptic and wanted these cases proved up to the hilt before being recorded. He did not agree that this was a case of sarcoma cured by Coley's fluid, and it would not figure in the Transactions as such.—Mr. WATERHOUSE concurred with the President in being absolutely sceptical with regard to Coley's fluid. His own experience was limited to 5 cases of inoperable sarcoma. In 3 of these cases rigors occurred and in 2 even with medium doses the patients had died from hyperpyrexia. It was therefore a most dangerous remedy and in no case did it do any good whatever. He related the case of a man suffering apparently from sarcoma of the lower third of the femur. He absolutely declined amputation, but he allowed an incision to be made into the mass, from which specimens were removed for examination. One portion was examined and it was declared to be a round-celled sarcoma, and another portion was sent to a well-known pathologist in Germany. He also reported that it was sarcoma. Nevertheless, two or three months later some suppuration occurred and a piece of necrosed bone came away. The patient recovered without Coley's fluid.—Mr. BATTLE, in reply, recalled that the patient was shown last year when about to undergo the treatment. His own impression at the time was in favour of a syphilitic origin, and he therefore put him on iodide of potassium in increasing doses until he was taking as much as 25 grains three times a day. This he did for two months without any effect whatever on the tumours. In order to satisfy himself as to the exact nature of the growth sections were taken from the tumour over the sternum and also from over the clavicle. These were examined by Dr. Jenner and by Mr. Shattock, and from both he received the assurance that it was a case of spindle-celled sarcoma with some large cells. While under iodide of potassium the tumours had been slowly getting larger and the arm had become greatly swollen from pressure on the vessels. Having heard of Mr. Moullin's case he thought it worth while, in the interest of the patient, to try the effect of the treatment, especially as no operative treatment could be thought of. The result they could see for themselves. The patient was now strong and healthy and no trace remained of the tumours. He asserted his belief that it was a case of spindle-celled sarcoma which could not have been dealt with in any other way.

Mr. BATTLE showed a woman, aged sixty-four years, who exhibited in a remarkable degree the phenomenon of Hepatoptosis. When she was erect the liver came down into the iliac fossa, and even when recumbent the hand could be passed above it under the ribs.

Mr. BATTLE also showed a man with Three Sesamoid Bones, which were shown by skiagraphy to be mainly bone in place of a patella.

Mr. BATTLE also showed a lad, fifteen years of age, exhibiting Genu Retrorsum. The weakness of the joint only dated back five weeks but was probably due to some defect of development of the upper epiphysis of the tibia. He proposed to fit him with a special knee-cap.

Mr. BATTLE also showed a patient with Multiple Fibrous Bodies all over the skin, especially of the trunk and head. On the head the growths were soft and nævoid in appearance.

PATHOLOGICAL SOCIETY OF LONDON.

Exhibition of Specimens.

A MEETING of this society was held on Nov. 15th, the President, Dr. PAYNE, being in the chair.

Dr. T. D. LISTER showed a specimen of Sarcoma of the Right Auricle of the Heart associated with Sarcoma of the Right Kidney from a child, aged four years. The symptoms had been of short duration, hardly a month having elapsed between the first symptom of abdominal pain and the death of the child. The growth was a small round-celled sarcoma with considerable extravasation of blood. He suggested that the growth was primary in the heart and secondary in the kidney.

Mr. T. CARWARDINE (Bristol) communicated a short account of a Tumour of the Rectum which he had treated with success by excision of the rectum. On clinical and naked-eye examination it had all the appearances of an epithelioma, but the microscopic and naked-eye sections, which were exhibited, proved it to be a spindle-celled sarcoma with some large round cells and giant cells. Very few such cases are recorded and Mr. Carwardine had not come across any similar one in Great Britain. Their authenticity had been doubted, but the specimen proved their reality.—Mr. A. E. BARKER mentioned a case of primary sarcoma of the colon in a man, aged twenty-six years. This was removed, but secondary nodules of a similar nature subsequently recurred.—Mr. STANLEY BOYD mentioned a case of alveolar sarcoma of the rectum in a woman.—Mr. TARGETT thought that such specimens were rare except as secondary to lympho-sarcoma. The type of such growths was in general that of a spindle-celled sarcoma.—Dr. HUNTER quoted another case of new growth of the cæcum which microscopically appeared to be a round-celled sarcoma. There were disseminated growths in various parts of the body, and those in the stomach had formed ulcers and were on examination found to be of the same nature.—Dr. ROLLESTON doubted the rarity of round-celled sarcoma of the digestive tract. He himself had shown a specimen in the œsophagus and referred to a specimen in the museum of the Royal Free Hospital, to a specimen of melanotic sarcoma shown at the society by Mr. Heaton, and also to its occurrence in white horses.—Dr. A. VOELCKER recalled a case of spindle-celled sarcoma in the ileo-cæcal valve of a child and another of melanotic sarcoma of the rectum. He did not think that sarcoma of the rectum was extremely rare.

Dr. WILLIAM HUNTER showed specimens of: (1) Thrombus in the Left Ventricle; (2) Embolus Impacted at the origin of the Right Common Iliac Artery; (3) Corresponding Veins Secondarily Thrombosed; and (4) Recent Infarcts in the Kidneys and Spleen from a youth, aged nineteen years, who died on the twenty-third day of illness from typhoid fever. A rigor had occurred on the seventeenth day of illness with agonising pain in the middle of the right thigh; five hours later the limb was of a dead white colour and no pulsation could be felt in the arteries of the foot. Gangrene supervened and a line of demarcation occurred in the middle of the thigh. In the left ventricle of the heart was a pale thrombus. Impacted at the point of origin of the common iliac artery was an embolus of pale colour, similar to that in the heart; the artery beyond and all its branches were filled with soft red thrombus. He commented on the comparative frequency of embolism in the above condition, emboli in the spleen being not uncommon, emboli in the kidney being less frequent, and emboli in the liver being still less frequent. He thought that the present case was due to embolism and not to thrombosis, the character of the clot in the common iliac artery closely resembling that in the heart.—Mr. STANLEY BOYD doubted whether this condition was due to embolism; he thought it more probable that the condition was due to thrombosis, and suggested that from the situation of the pain the occlusion of the vessel had first taken place at the level of the profunda and had extended from that point. This view was further borne out by the occurrence of thrombosis of the corresponding veins.—Dr. F. H. HAWKINS (Reading) quoted a case of occlusion of the middle cerebral artery giving rise to hemiplegia in typhoid fever and in the same case a clot was found in the auricle. He quoted another case and stated that Osler's view with regard to these cases was that they were thrombotic and not embolic.—The PRESIDENT did not consider gangrene as uncommon in fevers; he thought that there was considerable difficulty in ascertaining whether such a condition was due to an embolus or to thrombosis, but was inclined to the view that the changes which occurred in the blood tended to the occurrence of the latter.—Dr. HUNTER, in reply, said that a distinction ought to be drawn between small areas of gangrene which occur frequently in fevers and gangrene of a whole limb. He was still of the opinion that the blocking of the artery was due to embolism on account of the position and character of the clot in the common iliac artery.

Professor ROSE BRADFORD showed a specimen of Carcinoma of the Gall-bladder removed from a patient aged fifty-three years. No other growth was found except a small nodule in the head of the pancreas. No gall-stones were found in this case. The growth occupied the whole of the common

Digitized by Google

bile-duct and extended up into the hepatic ducts. The common bile-duct and the cystic duct were completely occluded. The hepatic ducts in the liver were greatly dilated. The interest of the case depended upon the absence of gall-stones. The patient from whom the specimen was taken was perfectly well till 27 days before admission; she then had pain in the right hypochondrium and in 3 days became jaundiced. The patient died two months after admission to hospital. The jaundice was persistent and he thought that this ought to have pointed to the presence of new growth rather than to gall-stones, which condition he had suspected during life.—In reply to a question by the PRESIDENT, Professor BRADFORD said that there was no cirrhosis of the liver, but that it was fatty.—Dr. VOELCKER doubted if the irritation of calculi would produce carcinoma in the gall-bladder, although they were commonly associated. In 6 cases of primary cancer of the gall-bladder biliary calculi were present in 5, and in 9 cases of secondary growth in the liver no gall-stones were found. He instanced the rarity of new growth in the kidney in association with calculus.—Dr. HUNTER quoted a case of primary cancer of the bile-duct round an impacted calculus. In two cases of primary cancer of the gall-bladder biliary calculi were present in both. He did not, however, believe that cancer was directly due to the irritation of the calculi.—Dr. ROLLESTON quoted the observations of Siegert, who had shown that in cases of carcinoma of the gall-bladder biliary calculi were present in 95 per cent., whereas in secondary cancer of the liver biliary calculi were only found in 50 per cent. He was of the opinion that gall-stones were the exciting cause of the new growth.—The PRESIDENT said that cancer of the whole alimentary tract seemed to be increasing, not only in the tongue and rectum, but also in the digestive organs.

Dr. WILFRED HADLEY showed two specimens of Malignant Disease of the Lung. In the first case the growth began in the peri-bronchial tissue at the root of the organ and was seen running along the bronchial tubes, especially at the upper portion of the lung. The mediastinal tissues were also involved to a less extent, and the whole lung was contracted down on to its roots, the pleural cavity being filled with sanious fluid. The corresponding portion of the diaphragm was infiltrated with growth to the thickness of an inch, and secondary deposits were found in the mesenteric glands and the liver. Microscopically the growth presented the well-defined appearances of scirrhous carcinoma. In the second case the growth apparently began in the pleuræ, both sides being almost equally affected. Patches of flattened, cartilaginous material, varying in size, were seen scattered profusely over both pleuræ. The root of the lung was hardly implicated and the bronchial tubes and peri-bronchial tissue showed no infiltration. There were, however, a few deposits of rather softer growth scattered throughout the lungs, notably one at the base of the right one. The outer surface of the parietal pleura was thickened with growth, but it had not affected the serous lining. Secondary deposits were found in the heart, kidneys, and arm. Microscopically the growth showed mostly the appearances of encephaloid carcinoma, though in portions there was little, if any, fibroid stroma. The cells were not well-defined epithelioma, but more like those seen in large round-celled sarcoma, whilst throughout the whole tissue a considerable admixture of lymphoid tissue could be made out.

Dr. A. C. LATHAM showed specimens of Multiple Abdominal Dermoids. Two specimens were shown, one a dermoid of the right ovary, the other a dermoid in connexion with the stomach. Both these specimens were removed from the body of a woman who had died from acute general peritonitis set up by the perforation of the dermoid of the ovary. There were also numerous other small dermoids in connexion with the stomach, the descending colon, and the suprarenals. Nothing abnormal was found in the structure of the walls of these cysts and no nerve cells were observed. Dr. Latham pointed out that this condition was very rare and that extremely few cases of multiple dermoids had been recorded. Kolaczek, Fraenkel, and Hulke had each described a somewhat similar case. In discussing the question whether such a condition could be regarded as a malignant one Dr. Latham mentioned a case recorded by Montgomery of a teratoma in which the author considered that the recurrence pointed to a malignant type, but concluded by regarding the above generalisation of an innocent tumour to be due to transplantation.—Mr. TARGETT doubted the malignancy of the disease. He had seen epithelioma develop in the wall of a dermoid. He thought that dissemination of dermoid cyst occurred through transplantation of the cells.

Dr. FREYBERGER showed the Brain and Head from a case of Embolism of both Middle Cerebral Arteries. The patient, a woman, aged thirty-nine years, had a paralytic stroke, in consequence of which she was completely paralysed on her right side and aphasic. Fourteen days afterwards she became suddenly comatose and died nine hours after the onset of the coma. At the post-mortem examination an embolus was found in the left middle cerebral artery; the thrombus was firmly adherent to the inner coat of the artery. There was a second and much larger embolus in the right middle cerebral artery, succulent, not adherent to the vessel wall. Numerous anæmic infarcts were in the spleen and kidneys. There were cancer of the pancreas and liver and recurrent vegetating endocarditis. The case was interesting on account of (1) the concurrence of cancer and endocarditis; (2) the embolism of both middle cerebral arteries; and (3) because of the difference in the appearance of the two emboli due to the retrograde changes having taken place in the first embolus, whereas the second was comparatively recent.

CLINICAL SOCIETY OF LONDON.

Primary Sarcoma of the Knee-joint.—Hyperpyrexia.—Excision of Intestine.—Restoration of the Ulna by Insertion of a Rabbit's Femur.

A MEETING of this society was held on Nov. 11th, the President, Mr. LANGTON, being in the chair.

Mr. HOWARD MARSH read a paper on a case of Primary Sarcoma of the Synovial Membrane of the Knee-joint. A man, aged twenty-one years, was in St. Bartholomew's Hospital in September, 1892, for a swelling on the inner side of the left knee of fourteen months' duration, situated over the inner condyle of the femur, close to its articular border. It was of about the size of a small flattened Tangerine orange. Its nature was doubtful, but it was regarded as probably due to tuberculous periostitis, with thickening of the adjacent parts. When cut into, however, it proved to be situated entirely in the subsynovial tissue and to be of the nature of a new growth. It was freely removed by cutting it out, together with a zone of surrounding synovial tissue. The wound healed without complication. Microscopic examination showed that the new growth was a mixed spindle- and round-celled sarcoma. In March, 1895, the patient was admitted with a recurrence of the growth, and a mass as big as a marble was dissected out from the upper end of the original scar. This had the same structure as the original growth. In December, 1895, a nodule of the size of a small walnut was removed from the subsynovial tissue to the outer side of the joint. In August, 1896, two small nodules of sarcomatous growth were removed from the inner side of the joint, and in October, 1897, two small masses of a similar nature were detected and removed. In December, 1897, a mass could be felt at the posterior part of the joint, apparently as large as a walnut. This had displaced the popliteal artery, so that it could be felt close beneath the skin. The patient complained of severe pain down the back of the calf. There was no affection of the femoral glands. As the limb was now almost useless, and as the growth was extending, amputation was performed through the middle of the thigh. On examining the joint a growth as large as a bantam's egg was found springing from the synovial membrane at the back of the joint, and there was a second but smaller mass extending forwards into the joint between the condyles. These growths, like those previously removed, presented a microscopic structure of a spindle-celled sarcoma with some small round cells here and there. Mr. Marsh remarked that the case was one of considerable rarity. He had not himself met with any other instance of primary sarcoma of a synovial membrane. The history of the case was remarkable; it extended in all over at least six years. The disease remained entirely local, and the various recurrences which took place involved different parts of the membrane, so that in turn the inner, an outer, and the posterior portions of the synovial membrane were involved. Up to the present time the patient had remained well.—Mr. JONATHAN HUTCHINSON, Jun., mentioned a case in

Digitized by Google

which he removed a sarcoma growing from the posterior ligament of the knee-joint. Recurrence took place in the posterior ligament within the year and there was also a firm series of nodules in the subcutaneous tissue of the thigh. Amputation at the hip was performed, but the patient did not survive. No secondary growths were found in the internal organs. He asked if the growth in Mr. Marsh's case was a pure sarcoma or a fibro-sarcoma. In some ways the case resembled those of "regional tumours" which recurred repeatedly in the same position but did not become disseminated. Such cases had been described by Mr. Hutchinson's father and by Sir Thomas Smith, and the speaker quoted one in which during several years tumours of sarcomatous structure developed repeatedly in the abdominal wall, but did not occur elsewhere.—Mr. HOWARD MARSH, in reply, said that the microscopic characters were those of a fibro-sarcoma. He thought that the cases mentioned by Mr. Hutchinson were those which Sir James Paget described in his "Surgical Pathology" as "recurrent fibroids"—tumours having fibro-sarcomatous structure, recurring locally eighteen or twenty times, but without recurrence in any internal organs. There was a case probably of this nature affecting the cheek now in St. Bartholomew's Hospital in whom such local recurrences had taken place three times and now the growth was too large for removal.—The PRESIDENT mentioned a case in which a "recurrent fibroid" had been removed twelve times from the foot, after which no further recurrences took place.

Dr. NEWTON PITT brought before the society a case of Hyperpyrexia in a Neurotic Woman with Bronchiectasis. The patient, a young woman, aged twenty-six years, had been troubled with chest mischief with abundant expectoration and hæmoptysis since the year 1891. Her condition was supposed to be due to phthisis, until she came under the care of Dr. Boswell at Faversham, when it was recognised that she had bronchiectasis; she then passed under the care of Dr. Anderson, who sent her to Dr. Pitt in 1895. She had periodic attacks of severe dyspnœa lasting for two or three days, preceded by a diminution in the expectoration. In these attacks the temperature was found almost always to be much higher in the left than in the right axilla, the difference amounting to two or four degrees. The difference on the two sides of the chest amounted to a degree or so, and at times on the left side the temperature ran up to 110°F. occasionally to 114°, and once even higher. The dyspnœa was so intense that the temperature, which was not excessive, could rarely be taken in the mouth. The patient was so prostrate during the attacks that it was not possible to carry out extensive and systematic examinations of any kind. The rectal temperature was not extreme. The temperatures changed within an hour or so and the patient was bathed in the most profuse perspiration, which was not limited to one portion of the body. It was noticed that at the acme of the attack the left palpebral fissure was smaller than the right. The appetite failed absolutely and the urine was extremely concentrated during an attack. The pulse-rate ran up to 140 sometimes. During a period of seven weeks, while the patient was under observation, the amount of general bronchitis varied from time to time, but there were physical signs of a cavity at the angle of the left scapula. No tubercle bacilli were present in the sputum, but staphylococcus aureus, another coccus, and a sarcina were found, the last-named being especially abundant. As an example of the temperatures it was noted once that when the temperature in the right axilla was 102° that in the left was 109·7° and in the mouth 99·4°. Many text-books refer to the albuminuria of fever. This is surely a misnomer, as when there is albumin in the urine it is, together with the fever, the result of a toxic process and is not proportional to the severity of the fever but to the intensity of the toxæmia. We ought to speak of toxic albuminuria. In this case there never was a trace of albumin in the urine in spite of the temperature being so high. The patient when last heard of was still liable to these attacks and she remained in much the same condition. Dr. Pitt did not wish to offer any explanation of these extraordinary temperatures, but merely to put the case on record. He thought that the temperatures were reliable and that the fact that with the temperature taken every four hours for many weeks by different people the more or less persistent difference between the temperatures in the two axillæ must be accepted as a fact. The extreme prostration of the patient and the dyspnœa present prevented her from taking the slightest interest in her temperature. In similar cases it has been suggested that the patient has artificially raised the temperature of the thermometer by friction, &c., but by any such means it is only possible to raise the temperature slightly, and it is quite impossible to do it without detection when a patient is under careful observation. In a similar case mentioned in a debate at this society by Dr. Mahomed in 1891, where a patient had temperatures of 114° on several occasions and once up to 128°, he came to the conclusion that there must have been fraud although he could not detect it. Still it is by no means certain that this conclusion was justified even in that case.—Sir DYCE DUCKWORTH wished for an expression of opinion from physiologists as to the possibility of such localised hyperpyrexia. All the recorded cases had been in women of a neurotic temperament and in many fraud on the part of the patient had been proved, and his own conviction was that the others were undiscovered frauds practised by mentally disordered patients, whose ingenuity in this direction was without limit.—Dr. BEZLY THORNE, with reference to the occurrence of unilateral symptoms in a neurotic patient, mentioned the case of a woman suffering from asthmatic attacks which came on rapidly, caused great alarm, and then passed off. On one occasion he found the heart beating under the right nipple although there were no signs of pleural effusion, an observation confirmed by Sir William Jenner. The condition could not have been due to transposition of the viscera as it passed off after a few days.—Mr. CLEMENT LUCAS mentioned a case in which a patient was detected heating the thermometer in a poultice and Dr. SIDNEY PHILLIPS one in which a cup of tea was used for a similar purpose.—Mr. D. DREW mentioned the case of a young woman who had been operated on for necrosis of the frontal bone and who had subsequently repeated attacks of hyperpyrexia, the temperature reaching 109°, for which no cause could be found.—Dr. KINGSTON FOWLER said that in nearly all cases of bronchiectasis there was some rise of temperature and dyspnœa attending any diminution of expectoration, but he had never seen the high temperatures described by Dr. Pitt. He observed that oral and axillary temperatures were unreliable, and in doubtful cases the rectal temperature alone could be trusted.—Mr. G. EASTES referred to the well-known case recorded in 1875 by Mr. Teale of Scarborough. Physiologists then denied that such temperatures were compatible with life.—Dr. PITT, in reply, said that his patient was so ill at the time that he thought that it would have been impossible for her to have played any tricks and she was most closely watched. In the Guy's Hospital Reports for 1893 Dr. Bryant had collected 100 cases of hyperpyrexia, including Mr. Teale's case.

Mr. CLEMENT LUCAS related the case of a boy, aged five years, from whom he had removed successfully 24½ in. of Small Intestine by the aid of a Murphy's button. The child had suffered every year from birth with bronchitis and from the age of a fortnight it had been noticed that there was a swelling on the left side of the scrotum which always remained irreducible. An operation on the hernia was attempted by a surgeon in the country on April 11th, 1897. Vomiting occurred on the following day and the patient's condition growing rapidly worse he was sent up to Guy's Hospital to be under the care of Mr. Lucas. The scrotum was much inflamed and peristaltic action could be seen beneath the skin. He was first seen by the assistant surgeon on duty, who laid open the scrotum and found fæcal extravasation and two wounds in the gut, which he attempted to close by suture, but did not reduce the bowel into the abdomen. The patient's condition remained critical and on April 17th it was found that the sutures had given way and that fæces were being discharged through the scrotum. In spite of great care the constant discharge of fæces caused ulceration of the surrounding skin. On April 25th the temperature rose to 104° but no general abdominal tension or tenderness occurred. From April 27th to May 18th the temperature ranged between 99° and 100°; almost the whole of the contents of the bowels were discharged through the fistula in the scrotum. On May 18th, 1897, Mr. Lucas determined to perform resection of the bowel with the object of restoring the continuity of the intestine, curing the fæcal fistula, and getting rid of the hernia. The bowels were cleared and the fæcal fistula was thoroughly washed out with an antiseptic lotion, then all the ulcerated parts were firmly bound up with aseptic pads. The skin of the abdomen being disinfected a central laparotomy incision was made under A.C.E. mixture. The bowel passing out and returning through the left inguinal canal was

Digitized by Google

surrounded by sterilised pads. On the parietal side the two pieces of bowel were ligatured near the internal abdominal ring and on the proximal they were clamped. Having divided between the clamps and ligatures Murphy's button was used to give end-to-end continuity to the bowel. The ligatured distal ends were further secured by turning in the mucous membrane and sewing over them. The pads were removed and the abdominal wound was sewn up. Attention was now turned to the scrotum, which was laid freely open, and the damaged and adherent bowel was separated by the fingers. The sealed ends within the abdomen were pulled through the inguinal canal. When detached and measured the bowel removed was found to be 27½ in. in length. The suppurating scrotum was thoroughly washed and packed with iodoform gauze. There was little to remark on in the subsequent progress towards convalescence. The temperature, which was 100° when the operation took place, fell to normal on the second day, and never again reached 100°. On the fourth day the laparotomy incision was found to be united primarily. Ten days after the operation the temperature became regular at 98·5°. As the button had not come away on the twenty-second day a dose of castor oil was given and it was passed on the twenty-third day after the operation. Mr. Lucas attributed the successful result in this case largely to the care which was taken to prevent any contamination of the laparotomy wound or peritoneum through the fæcal fistula, and to the method he adopted of closing the ends inside the abdomen before drawing the bowel out through the scrotum. The patient was shown at the meeting eighteen months after the operation in good health and free from hernia.—Mr. HOWARD MARSH mentioned a case of a child who had an abscess in connexion with the appendix which had existed for about a month. He opened it and then it did well for six weeks, and then fæcal extravasation occurred. He could not close the fistula which formed, so he performed laparotomy and excised the cæcum, joining the ileum to the colon by end-to-end anastomosis.

Mr. ARBUTHNOT LANE showed two cases illustrating the Restoration of the Shaft of the Ulna by the Insertion of the Femur of a Rabbit. One of the patients was a child the subject of a congenital abnormality of the shaft of the ulna. She had suffered from a progressive incapacity and deformity of the forearm and hand since birth. It hung in a position of considerable flexion and abduction when the child attempted to use it, which she did very imperfectly indeed. The ulna consisted of two separate parts, the pointed extremities of which overlapped and the axes of which varied considerably in direction. The lower end of the ulna was situated considerably above that of the radius. He exposed both fragments freely and separated them from the surrounding parts. Extension was made on the lower fragment till the hand assumed its normal position. The femur of a rabbit was split longitudinally and its halves were wired securely to the fragments so as to bring their longitudinal axes into their normal relationship to one another and to retain the lower fragment on a level with the lower end of the radius. The result of this operation was most satisfactory both as regarded the removal of the deformity and the restoration of the normal functions to the part. The second was that of a man, aged nineteen years, who lost the shaft of the ulna in 1896. He was admitted into Guy's Hospital in September, 1898, when the radiograph showed that there extended from either extremity of the ulna a fine spicule of bone. An incision was made along the length of the ulna and these spicules were exposed and freed from the soft parts in which they were embedded. A femur of a very large rabbit was then wired securely to the ends of the ulna, the spicules being included in the loops of wire. The result as shown by the skiagraph was most satisfactory, and Mr. Lane hoped at a later date to render the usefulness of the arm even more complete by removing some of the new bone which had been thrown out about the extremities of the ulna in consequence of the original inflammation.

OPHTHALMOLOGICAL SOCIETY.

The Accommodation Theories of Helmholtz and Tscherning.—Myxo-fibroma of the Optic Nerve Sheath.—Toxic Amblyopia due to Lead.—Exhibition of Cases.

AN ordinary meeting of this society was held on Nov. 10th, Mr. F. RICHARDSON CROSS, Vice-President, being in the chair.

Mr. PRIESTLEY SMITH read a paper entitled "The Accommodation Theories of Helmholtz and Tscherning: Suggested Explanation of their Discrepancy." He said that Tscherning's theory was sharply opposed to the generally accepted explanation but was based on very accurate observations. The question was whether the accommodation change in the lens depended on slackening of the zonula (Helmholtz) or on tightening (Tscherning). The anatomical arrangement of the parts concerned and nearly all clinical and experimental facts, especially the observations of Hess, which showed that during strong accommodation the lens was often tremulous and displaced downwards by gravity, strongly favoured the former view. Tscherning, however, had proved that during accommodation the anterior lens surface changed from a globular to a hyperboloid curve—that is, tended to become conical—sharper at the centre of the pupil and flatter towards the margin, and this, he contended could only be caused by tightening of the zonula supplemented by internal resistance at the pole of the lens. Mr. Priestley Smith's object was to show that this change could be equally well explained by slackening of the zonula. Let the case of an elastic circular hoop of steel first be taken. Traction at the sides transformed it into an ellipse; the curve flattens at the poles and sharpens at the equator, and somewhere intermediate between these regions was a point where no change took place. The position of this point and the general contour assumed by the hoop were governed by the varying resistance which it offered at different points. By modifying the resistance the curve could be modified at pleasure. Let the resistance at the pole be increased and the conical form observed by Tscherning was obtained; let it be increased towards the equator and the opposite effect—namely, a flattening at the pole and a sharpening of the curve elsewhere—was obtained. Mr. Priestley Smith exhibited a model consisting of an elastic hoop of metal bent so that it assumed in exaggerated form the shape of the lens during accommodation—namely, conicity of the anterior surface. It was strengthened with supplementary elastic strips in such a way that its resistance or rigidity increased progressively from the pole towards the equator. Traction at the equator, representing tightening of the zonula, reduced the conical to a spherical form. In the latter condition it represented the lens when subjected to the influence of the zonula; in the conical state it represented the accommodative change which occurred when the zonula was slackened by contraction of the ciliary muscle. It would be easy to theorise as to the resistance proper to the crystalline lens and to show reason for supposing that the arrangement of the fibres was such as to render the resistance progressively greater towards the equator, but Mr. Priestley Smith said he would not go beyond demonstrable facts. What he desired to show was that the changes which Tscherning had demonstrated with such admirable skill and ingenuity were not incompatible with the theory of Helmholtz. To his mind they were explained more satisfactorily by this theory than by any other.—Mr. CROSS, Mr. LANG, Mr. ERNEST CLARKE, Mr. BASS, Mr. DOYNE, and Mr. HARTRIDGE took part in the discussion.—Mr. PRIESTLEY SMITH said, in reply, that the continuous growth of the lens was inconveniently obvious in the enlargement and sclerosis of the organ with advancing age, both changes representing the steady development of enclosed epithelial elements in a site where there were no means of escape. The lens when free actually took the shape he had described, of which the model presented was a gross exaggeration. Helmholtz and Tscherning demonstrated the change in shape of the lens during accommodation by duplicating the image reflected from its surface. The anterior capsule was thicker than the posterior and the softness of the juvenile lens was very remarkable, needing the slightest force only to change its shape. He animadverted strongly on the manner in which Helmholtz's measurement of the antero-posterior diameter, 3·7 mm., had been copied into various text-books and monographs, whereas the more recent measurements, 4·5 to 5 mm., were much nearer the truth.

Mr. ARNOLD LAWSON reported a case of Myxo-fibroma of the Optic Nerve Sheath. The patient was a well-nourished girl, aged two years. The sight of the left eye had been thought defective for three months; it had been getting prominent for a few weeks. The personal health and family history were both good; the left eye was slightly prominent, but its movements were good and the pupil acted to light; the fundus was normal, except that the veins were rather full. Five weeks later there was decided proptosis, the pupil was inactive, the optic nerve was pale, and the eye was blind; the

Digitized by Google

movements, however, were good. From this time the symptoms progressed rapidly till the time of operation, five months after the first visit; the disc was then chalky white, the eye was proptosed forwards and slightly downwards, and the movements were strictly limited. The eye and contents of the orbit were removed; the tumour, which was as large as a partridge's egg, nearly filled the orbit and completely surrounded the optic nerve from the lamina cribrosa to the optic foramen. The child is now, six months after operation, in good health. The optic nerve was not involved in the tumour, which arose from the outer dural sheath. Microscopically the growth was found to be a myxo-fibroma. Mr. Lawson thought it inadvisable to attempt to save the eye in these cases; if the growth extended to the optic foramen, this latter should be scraped out. Myxo-fibromata were very rare; as a possible origin he suggested that a portion of the mesoderm intended to form the vitreous became included in the sheath of the optic nerve during its closure.

Mr. HERBERT H. FOLKER (Stoke-on-Trent) reported 5 cases of Toxic Amblyopia due to Lead which occurred among employés in the pottery district. 1. A female, aged twenty-six years, had worked in the dipping-house two years; on four occasions she had had symptoms of lead poisoning, colic, vomiting, and headache. Vision failed in the left eye and four days later in the right; the failure began with flashes of light and coloured vision and rapidly proceeded to total blindness. The pupils were dilated and inactive, the optic discs were pale and blurred, the retina was œdematous, and there were several hæmorrhages in it. There was some albumin in the urine. 2. A female, aged twenty years, six weeks after beginning work as a lithographer had headache and colic; after a year she had sudden total loss of colour vision, followed by sensations of flashes of light. There was typical neuro-retinitis with hæmorrhages. In this case vision improved. 3. A male, aged sixteen years, employed in the dipping-house, after two years had diplopia with headache, colic, and vomiting; the vision failed shortly after, and in six weeks he was totally blind. He also had coloured vision for a time and flashes of light. The optic discs were very white and the arteries were reduced to white cords. He had a trace of albumin and a gum line. 4. A female, aged eighteen years, employed in the dipping-house, after three years had headache and vomiting; the vision failed in one night; she had flashes of light of various colours. The optic discs were intensely white. 5. A female, aged eighteen years, employed in the dipping-house, had had for ten months several attacks of headache, colic, and vomiting; then the sight failed, and in two months she was blind. The optic discs were white and the vessels were small. In this series of cases all other toxic agents were excluded. None of the patients who had worked in the dipping houses responded to treatment, the case of the lithographer did; in the former the poison was introduced by absorption through the skin, in the latter by inhalation. With one exception all the cases experienced coloured vision. Treatment was by iodide of potassium or strychnine by the mouth or hypodermically.

The following cases were shown:—

Major M. T. YARR, R.A.M.C.: Case with Fundus Changes and Fibrous Tissue Formation in Vitreous, ? Congenital.

Mr. TREACHER COLLINS: Case of Monilethrix affecting Eyelashes and Eyebrows.

Mr. DOYNE: Case of Pigmentation of the Conjunctiva.

PATHOLOGICAL SOCIETY OF MANCHESTER.

Exhibition of Cases and Specimens.—Pathology of Cancer.

A MEETING of this society was held on Nov. 9th, Dr. R. B. WILD, the President, being in the chair.

Professor DIXON MANN showed an Aneurysm of the Abdominal Aorta in which rupture, accompanied by profound collapse, occurred three days before death. The patient recovered from the collapse and although the radial pulse could plainly be felt no pulsation of the tumour was perceptible. After death, which took place suddenly, it was found that subperitoneal hæmorrhage had taken place by which the pulsation of the aneurysm was masked and which also to some extent impeded the communication between the sac and the aorta.

Professor MANN also exhibited some Blood from a case of Acute Fatal Poisoning by Water Gas. The presence of carbon monoxide hæmoglobin was made evident by means of Kunkel's test (a 3 per cent. solution of tannic acid), and in order to afford a means of comparison a specimen of normal blood was treated in the same way. The blood which contained the carbon monoxide hæmoglobin yielded a precipitate of bright whitish-pink colour, whilst that thrown down from the normal blood was the colour of *café au lait*.

Dr. W. H. B. STODDART read a paper entitled "A Contribution to the Pathology of Cancer." The paper dealt with a case of cancer which had come under Dr. Stoddart's observation at Prestwich Asylum. The patient (an alcoholic dement) suffered for some months from obstinate constipation and died from perforative peritonitis. Post mortem a growth was found extending along the whole length of the mesenteric border of the stomach, small and large intestines, to the anus. It was limited to the intestine and microscopical examination showed it to be a spheroidal-celled carcinoma. Discussing the pathology of the case, Dr. Stoddart showed that there were two possible hypotheses to explain the anomalous distribution of the growth. The first was that the cancer began in the stomach, the rest of the intestinal tract being infected through the food-stream, the infective particles becoming arrested at the junction of the intestinal and mesenteric lymphatics; the second was that the whole growth arose on account of a rod of sub-notochordal mesoblast with dormant hypoblastic characters, assuming those characters in advanced life and giving rise to the epithelial growth. The specimen was shown, together with sections and microphotographs.

Mr. E. STANMORE BISHOP and Dr. FOTHERGILL showed an Ovary and Tube, with photo-microscopic sections and drawings. The specimen was removed by Mr. Bishop from a patient who had long suffered from pelvic mischief of infective origin following abortion. The clinical interest of the case lay in the fact that the symptoms and signs of ectopic pregnancy were exactly simulated. After an attempt to remove the mass by the vagina, during which a cyst containing blood was ruptured, the abdomen was opened, and after separating dense adhesions the ovary and tube were removed. The pathological interest of the case lay in the connexion which it illustrated between septic ovaritis and the origin of cystic disease of the oöphoron. The ovary was full of small cysts caused by the interrupted development of Graafian follicles, but closely resembling the early stages of ovarian cysts which are as a rule examined only when they have attained larger dimensions.

LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY.

Tetany.—Enteric Fever complicated with Pregnancy.—Pemphigus Foliaceus.—Exhibition of Cases and Specimens.

A MEETING of this society was held on Nov. 4th, the President, Mr. EDWIN LEE, being in the chair.

Mr. MAYO ROBSON read a paper on Tetany and Tetanoid Spasms associated with Gastric Dilatation treated Surgically. He related three cases and referred to others in which he had seen these complications associated with simple pyloric stenosis. He thought that the complications were much more common than was generally recognised, as attention had only been drawn to the more serious and almost universally fatal cases. In the cases which he related operation had been undertaken successfully and in all the cases intervals between the severe tetanoid attacks had been selected. He thought that the disease might be looked on more hopefully if the cases were treated surgically at an earlier period before the extreme manifestations of tetany had supervened.—Dr. TREVELYAN expressed a doubt as to whether Mr. Robson's cases could be really classed as genuine gastric tetany. Even Case 1, which resembled strychnine poisoning, was anomalous. He looked upon gastric tetany as a very rare disease. In the severe and dangerous attacks such as he had seen he thought that no other treatment was admissible than emptying and washing out the stomach, stimulation, and supplying the body with fluid by means of saline rectal injections or subcutaneous infusion, &c. He drew special attention to the fact very generally noted that the attack of tetany followed upon prolonged vomiting in cases of gastric dilatation. It was important to treat this vomiting, and if other means failed operative treatment directed to the gastric dilatation might have to be considered. Dr. Trevelyan looked upon the intoxication theory of gastric tetany as the most satisfactory,

Digitized by Google

but as yet it had not been definitely established.—Dr. CHURTON, while recognising the evidence of a connexion between gastric dilatation and tetany, thought that there must be some other factor necessary for the production of the disease, inasmuch as gastric tetany seemed to be extremely rare, although separately both gastric dilatation and tetany were common. Indeed, from cases which had been related to him recently during a consultation upon a case of typical tetany in a woman, aged forty-eight years, he inferred that this disease was of much more frequent occurrence in some districts than is usually supposed and that it was sometimes fatal.—Dr. CHEETHAM bore evidence as to the severity of one case of gastric tetany referred to by Dr. Trevelyan. There was no gastric dilatation, but the attacks always followed upon vomiting. The patient was now well.—Dr. GRIFFITH and Mr. LITTLEWOOD agreed with Dr. Churton as to the rarity of gastric tetany. Mr. Littlewood was under the impression that he had seen something of the kind in some cases after gastro-enterostomy.—Mr. ROBSON replied.

Mr. A. E. PEARSON described a case of Enteric Fever complicated with Pregnancy in a woman, aged eighteen years, who was admitted into the Leeds Fever Hospital on Sept. 8th, 1898. From the time of the cessation of the menstrual periods her health had been indifferent. She had suffered from morning sickness, which gradually became more frequent. There was also headache. On Sept 4th she took to her bed. On admission the temperature was 104°F. Signs of enteric fever, diarrhœa, meteorism, irregularly intermittent temperature, rapid pulse, and vomiting, especially in the morning, marked the succeeding days. Subsequently the vomiting and diarrhœa declined considerably until the third week of the patient's stay in hospital, when the vomiting became more frequent, the pulse was 140 to 160, and thready, and the meteorism rapidly increased. On several occasions the patient became so seriously collapsed that perforation was diagnosed, but under treatment the urgent symptoms subsided. In the fifth week marked jaundice supervened, there was considerable tenderness in the hepatic region, and the liver dulness appeared to be increased. On Oct. 12th as suppuration was suspected the liver was explored with a negative result. The patient aborted on the same evening. The fœtus measured about 4 in. in length and the placenta was adherent. The next day the patient was much easier. The vomiting ceased and the circulatory disturbance declined. The progress towards recovery was almost uninterrupted.—Mr. LITTLEWOOD, who had explored the liver, spoke of the harmlessness of the procedure.—Dr. TREVELYAN suggested that the jaundice was due to a typhoidal cholecystitis. Dr. WRIGHT, Mr. MAYO, and the PRESIDENT also joined in the discussion.

Dr. HELLIER read notes of a case of Pemphigus Foliaceus which attacked an apparently healthy female child on the ninth day after birth. The disease was virulent and rapidly fatal. On the tenth and eleventh days huge flaccid bullæ formed on the trunk, the face, and the limbs, and when the child died early on the twelfth day the skin of about half the surface of the body was either covered by enormous serous clots or entirely denuded of its cuticle. The child looked as though she had been scalded by boiling water. The cause of the attack was unknown. The mother was a healthy primipara and the father was a strong and healthy man. There was no specific history in either parent. The child was born in a healthy middle-class house and neighbourhood and received every care as regards cleanliness and nursing. There was no known source of navel infection. The mother made an excellent recovery from childbed. Dr. Hellier said that such cases are not necessarily specific. The disease is rare and very fatal. It is said to have occurred in epidemic form.—Dr. LIDDELL did not think that Dr. Hellier's case was one of syphilis, as it presented none of the distinguishing characteristics of that disease. Pemphigus neonatorum was considered to be due to septic causes in connexion with the surroundings of childbirth. Pemphigus foliaceus was a rare disease usually running a chronic course, while Dr. Hellier's case was one of exceptional rapidity. Under the term "dermatitis exfoliativa neonatorum" Ritter has described a class of cases in infants some of which bear a resemblance to pityriasis rubra, while others presenting flaccid bullæ like pemphigus foliaceus are regarded by some authorities as cases of that disease.—Dr. CHURTON referred to several cases of pemphigus and discussed the treatment.—Mr. KNAGGS mentioned a case in which continuous bath treatment was followed by recovery.—Mr. MAYO referred to a case and Dr. HELLIER replied.

The following cases, pathological specimens, &c., were exhibited:—

Dr. MANTLE: A case of Scleroderma with Rheumatic History.

Mr. MAYO ROBSON: Extra-uterine Gestation Sac at Eleventh Month removed entire.

Dr. HELLIER: (1) Uterus with Myomatous Tumour removed by Abdominal Hysterectomy; and (2) 30 Gall-stones removed by Cholecystotomy.

Dr. ALLAN: (1) Senile Uterus showing Ovarian Cysts; (2) Liver showing Malignant Disease, &c.; and (3) Kidneys from a case of Pernicious Anæmia.

Dr. CHADWICK: A case of Diphtheritic Peripheral Neuritis associated with Right Hemiplegia.

Mr. LAWFORD KNAGGS: Fibro-cystic Tumour of Uterus.

Dr. T. WARDROP GRIFFITH: (1) Specimen showing one of the possible relations of Mitral to Aortic Disease; and (2) Dissection of a Malformed Hand.

Mr. LITTLEWOOD: (1) Ovarian Cyst with Twisted Pedicle (specimen); and (2) Vermiform Appendix with Perforation (patient and specimen).

Dr. BARRS: A case of Spasmodic Torticollis.

Mr. MOYNIHAN: (1) Congenital Absence of Femur; and (2) Cyst of Kidney, partial nephrectomy.

Dr. TREVELYAN: (1) A case of Rapid Recovery from a Paraplegia due to Spinal Caries; and (2) a case of Relapsing Paralysis of One Leg of Obscure Causation.

Dr. WARDROP GRIFFITH showed a specimen of Gangrene of the Lung produced by the breaking down of a caseating bronchial gland which had caused a communication between the œsophagus and the lung. The patient was fifteen months old and was under treatment for cough. A widely distributed tuberculous lesion was found after death.

LIVERPOOL MEDICAL INSTITUTION.

Ringworm.—Exhibition of Specimens.

A MEETING of this society was held on Nov. 10th, Mr. F. T. PAUL being in the chair.

Dr. J. C. M. GIVEN communicated an interesting and well-illustrated paper on Clinical and Microscopical Varieties of Ringworm. After a *résumé* of the work done by various investigators up to the present time he gave a detailed account of his own researches, which consisted of a very thorough examination of 50 consecutive cases met with in the out-patient department of the hospital. He furnished a complete description of his methods, &c. His cases were arranged in three clinical groups: (1) cases in which the scalp was scaly and rough, with broken stumps of hairs showing a white sheath; (2) cases where the patches were smooth and there were few stumps; and (3) cases in which suppuration had occurred. His investigation was to ascertain (1) if these clinical varieties were associated in any way constantly with either of the three main varieties of the ringworm fungus and (2) whether the rapidity of cure was in any way related to the variety of fungus present. The microsporon audouini was found in 39 cases, or 85 per cent. Of these 31 were scaly, 5 bald, and 3 suppurative. The megalosporon endothrix was present in 15 per cent. The megalosporon ectothrix was not found in any scalp cases. In all cases of suppuration in the scalp the microsporon was found, including one well-marked case of kerion. When ringworm occurred in several members of the same family the parasite was always found to be of the same variety. He found that the ease with which the cases yielded to treatment in no way depended upon the variety of organism present. The paper was well illustrated by numerous excellent microscopic preparations and by a series of micro-photographic lantern transparencies.—Dr. G. G. STOPFORD TAYLOR had followed Dr. Given's investigations with great care and pleasure. The cases came from his (Dr. Taylor's) clinic and he could confirm clinically all Dr. Given had said.—Dr. BARENDT alluded to the confusion which still prevailed in this country as well as on the continent as to what should be the accepted criteria in deciding upon the plurality of the ringworm fungus. For his own part he considered he had evidence that megalosporon might become microsporon under modification of the culture media. He agreed that Dr. Given's three clinical types of ringworm were in the main correct and, like him, questioned whether a distinct variety of trichophyton produced always the same clinical results.—Dr. ABRAM, Dr. BUCHANAN, Dr. GRÜNBAUM, Dr. LOGAN,

Mr. PAUL, and Dr. N. RAW also entered into the discussion.—Dr. GIVEN replied.

Dr. ALEXANDER showed:—1. The Cerebellum of a boy, aged eleven years, with an Abscess occupying the greater part of the right hemisphere. Basilar meningitis was also present. The patient was brought by a drunken mother into the workhouse hospital a few days before death. Vomiting and retraction of the head were present and later coma supervened. No history was given and other circumstances prevented exploration being undertaken. Afterwards it was learnt that the boy had been operated upon for mastoid disease in another hospital a few weeks previously and had been discharged "well." 2. Three specimens of a rare variety of Sebaceous Tumour—probably an adenoma. They were all removed from the same subject and two of them were partially calcified. 3. Epithelioma of the Cheek and Ear. 4. Sarcomatous Epulis. 5. Papilloma of the Penis.

Mr. HAWKINS-AMBLER showed: (1) 132 Gall-stones which he had removed while exploring a carcinomatous gall-bladder; and (2) a specimen of Tubal Pregnancy removed by operation.

Dr. W. T. ALLEN exhibited a large Aneurysm of the Innominate Artery which caused death by rupturing into the pleura in a man aged forty-three years.

Mr. R. A. BICKERSTETH showed:—1. An Intra-testicular Hæmatocele as the result of an injury. A large quantity of blood had been effused within the tunica albuginea and the glandular substance of the organ was pressed aside. 2. A microscopic specimen of a Pedunculated Fibroma of the Tongue.

Dr. BUCHANAN showed:—1. Spermatozoa from Stains in Rape Cases. In one specimen the stains were recent, in another thirteen months old. From both excellent specimens of spermatozoa were obtained. 2. Microscopic Interstitial Fibroids of the Uterus.

Dr. E. T. DAVIES showed what is happily nowadays a rare pathological specimen—an enormous Ovarian Cyst removed post mortem from a woman, aged thirty-three years. She had persistently and absolutely refused operation. The abdomen became enormous, the legs were swollen and cracked and discharged great quantities of serum. Emaciation became extreme and dyspnœa great. She died somewhat suddenly from rupture of the cyst. Post mortem the peritoneal cavity was found to be full of ovarian fluid. The tumour was the usual multilocular cyst with one large and many small cysts, and could have been easily removed, there being no important adhesions.

Dr. T. B. GRIMSDALE showed a microscopic section of the Uterine Scar two months after Cæsarean section. The patient died from carcinoma of the rectum, for which colotomy had been done some months previously. Post mortem the silk sutures in the uterus were found to be surrounded by small, whitish, nodular growths, which were thought to be cancerous, but the microscope showed them to be fibrous, and the question was raised whether silk was more likely to produce these irritative fibromas than was catgut.

Mr. THELWALL THOMAS exhibited a Tuberculous Kidney removed by Nephrectomy. It contained several small abscesses and miliary tubercles were dotted all through it.

A considerable discussion followed, in which Mr. PAUL, Dr. WARRINGTON, Dr. ALEXANDER, Dr. E. T. DAVIES, Mr. A. E. DAVIS, Dr. CARTER, Mr. LARKIN, Dr. ARCHER, and Dr. BUCHANAN took part.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

Exhibition of Cases and Specimens.—Tuberculous Neuritis.—Acute Yellow Atrophy.

THE first meeting of the seventy-eighth session of this society was held on Nov. 2nd, Dr. WILLIAM CRAIG, Vice-President, being in the chair.

Mr. ALEXIS THOMSON showed a patient after Resection of the Pylorus. She was the subject of a large and visible pyloric tumour of eight months' development when she came under notice. Pyloric carcinoma was diagnosed; it seemed so large as to be quite beyond surgical relief, but it was considered advisable to have a look at it. There was no dilatation of the stomach; simple diet could be taken; there was not much sickness nor much pain; her weight had fallen from 12 st. to 8 st. 3 lb. On operating a large carcinomatous tumour of the pylorus was found and removed; there were no glands involved. It was the largest tumour Mr. Thomson had removed in cases of pyloric carcinoma. Since the operation in July the patient had gained 2 st. 4 lb., never had an untoward symptom or pain, and is now perfectly restored to health. The operation was performed by Kocher's method, a Murphy's button of ⅞ in. being used, which was passed on the thirteenth day.

Dr. ALLAN JAMIESON showed a case of Tylosis of the Palms and Flexor Surfaces of Both Hands, associated with hyperidrosis and with nævus neuroticus. For the latter condition nothing had been done, but for the ichthyosis manifestation—i.e., the tylosis—resorcin plaster had been applied and pumice rubbed on. The hands had under this treatment become soft and the fingers could be extended.

Dr. AITCHISON ROBERTSON showed a large Tonsillar Calculus, in length about 1½ in. and in weight about 1 oz.; it was probably the largest yet recorded. For many years the patient had been subject to repeated attacks of tonsillitis; ultimately, outside the neck, a large abscess formed, which was opened. Some glands were at the same time removed; the opening healed well, and there was no more tonsillitis or other trouble for two years. The patient then gradually felt difficulty in swallowing; suddenly one night he was awakened by a choking sensation and the accompanying violent cough resulted in the extrusion, without any hæmorrhage, of the large calculus shown. There could be felt a depression in the tonsil in which the calculus had been embedded.

Dr. ALEXANDER JAMES read a paper dealing with the clinical aspects of Tuberculous Neuritis He noted that any part of the nervous system might be affected—cranial nerves, phrenics, &c. It was remarkable for its tendency to appear, disappear, and again reappear. On account of this transitory character it was by many said to be a hysterical manifestation. Now it was generally ascribed to vaso-motor changes. Dr. James, however, thought that the affection was due to poisoning of the nerve tissues by tuberculous toxins. The condition had been discussed by many observers. He narrated several cases in illustration of his thesis. The first case was that of a man, aged forty years, with well-marked phthisis and hæmoptysis. The skin sensibility over the legs and feet was slightly impaired; formication had been present and there was a degree of tenderness in the muscles. Evidences of neuritis became more marked in both legs, as shown by drop-foot, loss of power of extension, and pain in the muscles. The reflexes were absent and electrical reactions diminished. In this cases the motor paralysis was greater than the sensory. The second case showed that sensory tracts may be more affected than the motor. The patient was a boy, aged sixteen years, suffering from lupus and tuberculous disease of the tarsus together with advanced phthisis. The larynx was so affected that tracheotomy had to be performed on account of the stridor and dyspnœa. Shortly after this he lost feeling in the right arm and leg and to a lesser extent in the right side of the face. There were no motor affections. This condition lasted three days but had entirely disappeared in a week. A month later, however, the right arm and leg were numb and to a less extent the right side of the face and trunk. Sensibility to heat and touch were also lessened. He complained of pain on the right side of the head when it was combed. The muscles of the affected arm and leg were tender and wasted. The knee-jerks were increased, especially on the right side. The third case was that of a man, aged twenty-two years, a miner; the motor nerves were chiefly affected, but the duration was short. He complained of loss of power in the left arm during four months with stiffness of the wrist. He exhibited marked disease of the left lung. The left arm as a whole was distinctly smaller than the right, the muscles being considerably atrophied and paralysed. The sensibility to touch, pain, and temperature was hardly affected, but the muscles were painful. Electrical and reflex excitability were increased. The left knee-jerk was more marked than the right and ankle clonus was present in the left leg. The left wrist was affected by tuberculous disease. Under treatment the motor power increased remarkably. The fourth case was that of a stable-boy, whose illness began suddenly five months previously with pain in the left foot without history of sprain. Next morning the foot was swollen and painful. The swelling went down under treatment but the pain remained. He looked healthy and no disease was evident except slight thickening on the inner side of the left tarsus. Sensation was normal, but voluntary

Digitized by Google

power in the left thigh and leg was impaired and the muscles were atrophied. The knee-jerks were exaggerated in both legs but especially in the left. Electrical excitability was lessened. He improved for a time, but the left tarsus showed marked tuberculous disease and the left foot required amputation. The increased irritability gradually lessened in degree until in six months it had gone from the right leg. The cause of the irritability was doubtless due to some slight sclerosis in the lower part of the cord together with poisoning as a result of tuberculous toxins. In many of the cases of causeless hemiplegia which occurred in the course of tuberculosis and which might last only two or three days a tuberculous meningitis might be present. Such cases also occurred, however, where there had been no meningitis or anything to account for the hemiplegia. It was said by many that such cases of hemiplegia were due to vaso-motor changes, as œdema of the brain. Dr. James thought, however, that they were much more probably due to the action of tuberculous toxins. In tuberculous meningitis occurring in children paralyses might be largely due to toxins. The patient might exhibit very few symptoms but suddenly develop convulsions or coma and might die. In such cases no evidence of brain or heart disease might be found but tuberculous disease was present, as happened in the following case. A male, aged fifty years, was found lying on a seat unconscious. The condition was not due to the action of any drugs. It became known that he had been troubled with a slight cough for some time. On shaking him he was able to give his name and address. The pupils were small and there was ocular divergence; no spasticity was present; rhonchi and râles were present over the chest. After the administration of whisky he had a fit and remained in the opisthotonic condition for fully a minute. The pulse became much weaker; three fits followed at short intervals and he died three hours after having been first seen. The brain tissue was very œdematous. In the lungs there was extensive tuberculous disease, but the other organs were healthy. Other possible causes for death might be suggested, but Dr. James thought that such cases were examples of general nerve tissue poisoning by tuberculous toxins. The mental stupor which came on towards the end of most cases of phthisis might have the same origin. Of course, the toxic effects might be due to other organisms besides those of tubercle bacilli. The conclusion which he arrived at was that a tuberculous toxin was produced which might cause more or less distinct effects on the nervous system.—In the course of the discussion which followed Dr. GRAHAM BROWN recalled a case of sarcoma accompanied by toxin poisoning. At first the patient had no symptoms of any diagnostic value; when he died numerous sarcomata were found, many in the skin, one at least in the liver, one in the stomach, and one in the abdominal cavity. What had led him to seek advice was a patch of anæsthesia on one foot; there was a further area of anæsthesia on one little finger. There was atrophy of the right shoulder and of the left forearm and hand. Dr. Graham Brown considered the condition closely simulated poliomyelitis anterior acuta and was due to a toxin poisoning of the cells of the anterior cornua, and that it could not have been a tumour growing in the cord and attacking only the anterior horns and missing the white matter.—Dr. R. A. LUNDIE said he could almost wish another title had been chosen, for neuritis had such a definite pathological meaning. The term neuritis might be appropriate to some of the cases, yet such a title did not cover all the ground. The chief symptom in one case he had in mind was an anæsthesia over one-half of the body and strictly limited to that half; such might be hysterical and quite came under the class of cases called "hysterical." They were not warranted in calling a disease developed all over one-half of the body a neuritis.—Dr. CHURCH suggested the possibility of phrenitis as a cause of the rapid death in some tuberculous cases and asked if the phrenic nerves had been examined in the instance of the death due to rapidly-acting toxin.—Dr. FLEMING said that the cases of most interest were those of multiple neuritis in tuberculosis. In any debilitated individual the mere bending up one arm for long enough would cause ulnar anæsthesia. In tuberculous cases people were very likely to be infected by other toxins; many, however, did not die from toxin poisoning. Why did so many escape? He thought the hemiplegia cases were probably hysterical and not neurotic.—Dr. JAMES, in reply, said that with regard to Dr. Graham Brown's narration of the case of sarcoma he agreed that in malignant disease there were toxins circulating and producing changes, and that in the end there was a toxin produced which clouds over the nervous system. Why the toxin should fall on certain parts was difficult to explain, but this was the way with all toxins—e.g., those of locomotor ataxia and lateral sclerosis. As regards Dr. Lundie's criticism Dr. James said he meant an inflammation of nerve tissue as G. H. Lewis used the term—an inflammation not limited to peripheral nerves, but affecting the whole tract of the cerebro-spinal axis. As to the possibility of phrenitis he thought that as this toxin affects the whole nerve tissue death might be due to the toxin affecting the respiratory centre in the medulla.

Dr. ROBERTSON DOBIE read a paper on Acute Yellow Atrophy, in which he reported a case of a rare disease which had occurred in his practice in the summer and which he had diagnosed as one of acute yellow atrophy. The unique points of the case were the clearness of mind maintained throughout the illness, the absence of delirium, the ultimate reappearance of the normal liver dulness after it had entirely disappeared, and the return to good health. For the excessive internal hæmorrhages Dr. Dobie had given oil of turpentine freely and to the use of this remedy he attributed the successful result.

SOUTH-WEST LONDON MEDICAL SOCIETY.—At a meeting held on Nov. 9th at Wandsworth, Dr. J. J. Macwhirter Dunbar, President, in the chair, Mr. Macleod Yearsley read a paper on Chronic Discharges from the Ear and their Treatment. He confined himself to discharges from the ear which have become chronic, pointing out that the offensive nature of the discharge is of less value in diagnosis than the rapidity of the disappearance of the fœtor under simple antiseptic treatment, the persistence of fœtor usually pointing to the retention of pus in the antrum or the presence of caries of the ossicles or temporal bone. Discharge in both ears, appearing without pain in a weakly child, suggests tubercle. The plan and method of careful diagnosis were pointed out with reference to attention being paid to the following points: the presence of polypi or granulations, the locality and size of perforations in the membrana tympani, the condition of the rest of the membrane, the condition of the inner wall of the tympanum, and the condition of the external auditory meatus. Perforations of the superior posterior quadrant of the membrane are often associated with caries of the incus, a bone specially liable to caries because, probably, of its blood-supply being more easily cut off owing to inflammation of the reflected mucous membrane, from which it gets its supply, whereas the malleus being partly in the substance of the membrana tympani and the stapes being attached in the fenestra ovalis have a better supply. The principal complications of chronic middle-ear suppuration are granulations, polypi, disease of ossicles and temporal bone, mastoid involvement and cholesteatoma, and the sequelæ—meningitis, cerebral or cerebellar abscess, lateral sinus, thrombosis, and pyæmia. In regard to treatment the removal of post-nasal adenoid growths is often of more importance in adults than in children, the thorough cleansing of the tympanic cavity by removal of polypi or granulations, &c., which may block up the passage and retain pus, and the thorough cleansing of the cavity by means of gentle syringing of the ear with hot antiseptic lotion, such as carbolic acid, 1 in 40; lysol, 1 per cent. to 2 per cent.; resorcin, 2 per cent. to 3 per cent.; boric acid, 1 drachm to a pint; perchloride of mercury, 1 in 3000 to 4000; or permanganate of potassium three or four times a day when the discharge is profuse, may be sufficient to cure simple uncomplicated cases. For other cases the use of hot instillations once or twice a day of carbolic acid, 1 part to 15 parts of rectified spirit and 15 parts of water; perchloride of mercury, 1 in 1000 parts of water, or in 25 parts each of water and rectified spirit; resorcin, 4 per cent.; salicylic acid, 1 in 200 of water or 2 per cent. to 5 per cent. of spirit (but this drug may produce a severe inflammatory reaction); boroglyceride, 10 per cent. to 50 per cent. solution; or a 6 per cent. solution of peroxide of hydrogen may be employed. The patient is laid upon the sound ear, the solution, comfortably warm, taken up in a dropper and a little poured into the diseased ear, retained for ten minutes, the tragus being pressed backwards and inwards to force the fluid through the perforation when this is small. The instillation of warm rectified spirit, diluted at first and increased in strength as

Digitized by Google

it is borne, is a valuable agent, especially where antiseptic instillations fail and in cases where no caries is present. The operation of ossiculectomy was described and recommended for cases of persistence of discharge with perforation in Shrapnell's membrane due to caries of the head of the malleus with disease of the incus or the anterior attic wall before resorting to the mastoid operation.—A discussion followed in which the President, Dr. Duke, Dr. Barkwell, Major Mark Robinson, I.M.S., and Mr. Gay took part.—A fine collection of specimens illustrating the lecture was shown and a very cordial vote of thanks was accorded to Mr. Yearsley.

MIDLAND MEDICAL SOCIETY.—A meeting of this society was held on Nov. 2nd at the Medical Institute, Birmingham, the President, Dr. W. G. Lowe, being in the chair. The following gentlemen were elected members of the society: Mr. H. D'A. Ellis, Mr. R. H. Gilpin, Dr. F. V. Milward, Dr. A. Croll, and Mr. F. J. V. Hall.—Mr. Chavasse showed a case of Ectopion Vesicæ. The patient was a girl, aged four years. Various plastic and osteoplastic operations had been unsuccessfully performed. In December, 1897, Mr. Chavasse separated the ureters from the bladder and transplanted them into the vagina and cut away the posterior wall of the bladder. The remaining cleft was closed at a later period by Thiersch's method. The urine passed into the vagina and was caught in a urinal applied to the vulva.—Mr. J. T. J. Morrison showed a man, aged twenty-four years, who on Oct. 4th had been kicked on the upper and inner angle of the left orbit by a pony whilst he was stooping down behind the animal. The blow, which was not very forcible, appeared to have been struck by the inner calkin of the shoe on the near hind foot. Soon after the injury both the left eyelids began to swell and some hours later the swelling greatly increased when the patient was blowing his nose and a little blood-stained mucus came from the left nostril. When seen on Oct. 7th there was considerable surgical emphysema of the left eyelids and pressure on the upper and inner part of the orbit caused pain. There was also some proptosis (noted by Mr. Priestley Smith), but no diplopia. No sign of bruising could be seen. The history and appearances excluded injury of the frontal sinus, antrum, or nasal bone; the air must therefore have escaped from the anterior ethmoidal cells as a result of fracture of the posterior portion of the lacrymal bone, or adjacent part of the os planum of the ethmoid, or both these bones. A pad of wool was applied to the lids and the nostril was irrigated daily with izal lotion. In a week all traces of the injury had disappeared.—Mr. Haslam showed a Tumour of the size of a hen's egg which he had removed from the penis of a man, aged forty-three years. Ever since the patient could remember he had had a small lump on the right side of the penis just in front of the scrotum. For some time this had been gradually increasing in size and for the last two months its growth had been rapid. On admission the tumour was found to be attached by a broad base to the right corpus cavernosum on its lateral and ventral aspects, but was not interfering in any way with the urethra, though at the operation it was found to be very close to this. On section after removal the tumour had all the appearances of a fibro-myoma of the uterus, and its structure, as shown by the microscope, consisted of fibrous tissue with a very large proportion of involuntary muscular tissue.—Dr. Lamb read a paper on the Diagnosis of Suppuration in the Accessory Cavities of the Nose. For diagnostic purposes he divided the cavities into an anterior group which drain through the hiatus semilunaris into the middle meatus, and a posterior group which drain into the olfactory fissure and naso-pharynx. He described the systematic examination of the various cavities including transillumination, the manipulations necessary in catheterising them through the natural openings, and the operation of exploratory puncture in certain cases.

BRITISH LARYNGOLOGICAL, RHINOLOGICAL, AND OTOLOGICAL ASSOCIATION.—A meeting of this society was held on Oct. 28th, Dr. J. Middlemass Hunt, President, being in the chair.—The President showed a case of Epithelioma of the Larynx (with microscopical specimens) occurring in a man, aged forty-four years, who had suffered from increasing hoarseness for six months and was now quite aphonic. On examination the anterior commissure was seen to be occupied by a pedunculated growth.—Dr. Hunt proposed to perform thyrotomy and to remove the growth and surrounding parts.—Dr. Furniss Potter showed a case of Black Tongue in a man, aged forty-eight years. A dark patch was seen on the dorsum immediately anterior to the circumvallate papillæ, which consisted of epithelial and food débris, apparently pigmented and adherent to hypertrophied papillæ, which latter terminated in hair-like processes about ¼in. long. Dr. Potter also showed a case of Loss of Abductor Movement in the Left Vocal Cord. The patient who is a healthy-looking man, aged thirty-three years, had been under treatment during the last two years for chronic pharyngitis and nasal polypi. There was no history of syphilis—or (with the exception of influenza four years ago) any previous illness. On examination the left cord was seen to be motionless and practically fixed slightly to the left of the middle line, the right cord overlapping the middle line to meet the left on phonation. The chest had been examined but no sign indicating intrathoracic pressure had been discovered. The knee-jerks and pupil reflexes were normal; in fact, there was complete absence of any sign or symptom to indicate the cause of loss of motor power.—Dr. Whistler suggested that pressure on the recurrent nerve might be caused by enlargement of one of the laryngo-tracheal glands.—Mr. Mayo Collier cited a case in which paralysis of a vocal cord was caused by an empyema situated over the apex of the lung and in which motor power returned after surgical treatment of the empyema.—Mr. Mayo Collier exhibited a case showing Deformity of the Palate, Teeth, and Face due to early Nasal Obstruction. The patient, a man, aged eighteen years, presented a markedly typical appearance of the effect of chronic nasal obstruction on the growing skull.—Dr. Milligan read the notes of a case of Suppurative Catarrh of the Right Maxillary Antrum and Right Frontal Sinus in which at the time of operation on the antrum, though a careful examination was made, frontal sinus suppuration was not diagnosed.—The President delivered his inaugural address on "An Appreciation of Three British Aurists—Wilde, Toynbee, and Hinton," dwelling strongly on the respect in which these workers were held by continental authorities on aural surgery.—Dr. Milligan described two cases of Extradural Abscess following Chronic Suppurative Middle-ear Disease.—Dr. Dundas Grant showed a case in which he had removed an Epithelioma from the auricle.

ULSTER MEDICAL SOCIETY.—The opening meeting of this society for the session 1898–99 was held on Nov. 3rd. The retiring President, Dr. J. A. Lindsay (who was accorded a very cordial vote of thanks for his admirable management of the affairs of the society during the past year) introduced his successor, Dr. Joseph Nelson, who delivered his presidential address. After thanking the members for the high honour conferred upon him in electing him President of that old and honourable society, Dr. Nelson said that in thinking over what was the best subject to bring before them he had decided, as the great majority of the members were general practitioners, to treat certain subjects which were of mutual interest to them and to specialists like himself. He then discussed very fully the three topics of (*a*) ophthalmia (blennorrhœa) neonatorum, (*b*) mastoid disease, and (*c*) middle-ear suppuration. With reference to all three he emphasised the importance of prevention. In regard to the ophthalmia of newly-born children he said it was lamentable, notwithstanding Credé's well-known teaching, that blindness was so common owing to a purely preventable disease. It had been thoroughly dealt with in maternity hospitals, but it was among the poor treated in their own homes that its ravages were especially seen. He dealt with the preventive measures to be adopted in reference to mother and child. As to mastoid disease he showed its important bearing on affections of the brain and narrated a case treated by himself so far back as 1883 in which a most successful result had been obtained by opening through the mastoid antrum and evacuating and draining an extradural abscess. Dr. Nelson then discussed very fully the important subject of middle-ear inflammation, its relation to throat affections, its connexion with general diseases such as scarlet fever, and its prophylaxis and treatment. The address was full of practical remarks and suggestions, and at its conclusion Professor Symington moved a hearty vote of thanks to the President for an address the practical nature of which, he was sure, was very much appreciated. He stated that he (Professor Symington) was the first British anatomist

Digitized by Google

to direct attention to the mastoid antrum.—Mr. W. G. Mackenzie seconded the vote of thanks, which was most cordially passed by the large audience of medical men present.—The President having thanked the members it was decided that the annual dinner should be held on Nov. 24th. Several new members were then elected.

BIRKENHEAD MEDICAL SOCIETY.—A meeting of this society was held on Nov. 11th, the President, Mr. H. Nazeby Harrington, being in the chair.—Mr. Ellis Pearson opened a discussion on the Practical Application of Antiseptics in General Midwifery Practice. He maintained the extreme desirability of midwifery nurses having a general training in surgical nursing before their special training in order that they should become thoroughly imbued with antiseptic principles. As a lubricant for obstetric work carbolic acid with vaseline (1 in 20) was suggested as one against which the usual strong objections to most lubricants could hardly lie. Washing of the pudenda by the nurse before labour with some fairly powerful disinfectant was recommended as a procedure which, though it might at first sight seem fussy, would probably in these days of spreading knowledge concerning germs be accepted without demur by intelligent patients. Douching Mr. Pearson held was best limited in normal cases to one douche given immediately after labour by the practitioner himself; at the same time he considered (always provided that the nurse could be thoroughly trusted) that regular douchings throughout the puerperium were desirable because they prevented many of those evanescent appearances of slight pyrexia, which cause the medical attendant so much anxiety.—The discussion was continued by Dr. Marsden, Mr. Stansfield, Mr. Wilkinson, Dr. W. Floyd, Mr. Vacher, Dr. Brien, Mr. Laird Pearson, and the President.

Reviews and Notices of Books.

The Eye as an Aid in General Diagnosis: a Handbook for the Use of Students and General Practitioners. By E. H. LINNELL, M.D. Philadelphia: The Edwards and Docker Co. 1897. Pp. 248.

IN giving Dr. Linnell credit for taking much trouble in collecting a large number of facts showing the relations of affections of the eye to particular diseases of the general system we doubt the utility of the work to either the student or the general practitioner. A few years ago Professor Knies of Freiburg-in-Baden took the same subject into consideration and wrote a very good treatise upon it, but treated it in a manner exactly opposite to that adopted by Dr. Linnell. Taking the diseases of the several systems of the body—as the digestive, respiratory, circulatory, and nervous systems—he described the affections of the eye which they are severally liable to induce. Dr. Linnell, on the other hand, takes the several diseases of the eye and endeavours to show their value as a means of enabling a diagnosis to be made or, rather, of assisting a diagnosis to be made. The difficulties which present themselves, however, are very numerous and great. Taking, for example, one of the first subjects mentioned by Dr. Linnell, "ocular paralysis," it scarcely helps our diagnosis to be told that whilst tabes and syphilis are responsible for the larger number of cases, yet paralysis of one or more muscles may result from multiple sclerosis; that it may be the consequence of diabetes and renal affections; that it may be rheumatic or may follow diphtheria; that in the latter case it is usually peripheral and is the sequence of hæmorrhages or neuritis, but is sometimes nuclear; and, finally, that an ocular paralysis due to peripheral neuritis "is most frequently caused by alcohol and we should expect to find associated symptoms of peripheral neuritis in other localities." We fear that a reference to this chapter would give little assistance to a well-instructed practitioner who meets with a case of paralysis of the third nerve, beyond the suggestion of a number of conditions to which it might be owing.

The author especially disclaims any discussion on the differential diagnosis of the various forms of disease of the fundus of the eye on the ground that such a diagnosis requires special training and skill not possessed by the majority of general practitioners, yet he immediately proceeds to consider the features common to several varieties of retinitis and the appearances presented by choked disc as well as those seen in ocular affections caused by drugs which are not recognisable and certainly not distinguishable without a considerable amount of special skill in the use of the ophthalmoscope. Yet it is in these very cases that the eye symptoms sometimes afford important aid in diagnosis.

Researches on Leadless Glazes. By W. J. FURNIVAL. Stone, Staffordshire: W. J. Furnival. 1898. Pp. 132. Price £5 5*s*.

LEADLESS glazes for pottery ware seem to be coming to the front and to be likely to take an important position in the future. So recently as 1893, when the Asquith Committee held its inquiry into the "dangerous trade" of pottery manufacture, there was only one "leadless" glaze submitted to a member of the committee and that one proved to contain considerable quantities of lead. Since then Messrs. Minton have stated that they have successfully used a leadless glaze and have exhibited the result, and we have now this work by Mr. Furnival containing a large number of practical trials and receipts, many of which seem to be very successful. Consequently, those who limited their hopes of improvement in this industry to the introduction of fritted lead glazes will go further and begin to ask for the absence of lead altogether.

Readers of THE LANCET do not require to hear again the oft-told story of the lead poisoning in the Potteries due to dipping and painting the ware with glazes and colours containing "raw"—that is carbonate of—lead or to be reminded of the proposals made to diminish this danger by fusing or fritting the lead into a glass before use. That this precaution, if properly carried out, will largely diminish, if not remove, the danger of lead poisoning has been shown both by experiments on the solubility of frits and by the practical experience of certain large firms who have adopted them, and as this involves a comparatively small change in the present process of manufacture reformers have been content to ask this of the manufacturers and no more. Unfortunately, in most cases they have not even got this much, and if successful experiments continue to be made with leadless glazes, will probably, as so often happens in the history of reforms, demand and ultimately get much more than they originally hoped for. Mr. Furnival is himself connected with the pottery trade and has obviously a close practical acquaintance with its working processes and the difficulties to be overcome. He is evidently enthusiastically in favour of leadless glaze and has made hundreds of practical experiments the results of which will be found in the latter part of the book. He has very wisely published his failures as well as his successes so as to save others the tedium of passing over the same ground, but the percentage of successes is very large. The experiments have all as nearly as possible been made under practical working conditions and he discusses very fully the difficulty of ensuring absence of lead during the grinding of the leadless glaze, or its fritting, or even the possibility of lead fumes entering the glaze during subsequent baking. In fact, he seems to have considered all the difficulties and looked out for all the defects of which a glaze is capable and to have met them successfully in a certain number of his receipts. The earlier portion of the book is less important, but contains an interesting history

Digitized by Google

of leadless glazes with perhaps a somewhat too copious quotation from well-known authorities.

Taking the work altogether it is a valuable contribution to the subject and has only one serious defect. The author has published it at the almost prohibitive price of £5 5*s*. Surely it would have been better to have either regarded his receipts from a purely commercial point of view and sold them as trade secrets or to have published his book at a reasonable price and given the result of his experiments freely to the world. This, however, is a small matter and the experimental results are here, and the practical reformer will ask, What next? The reply is probably, Nothing, unless the Home Office can be persuaded to seriously undertake the work of reform on the lines more than once laid down in these columns.

The *Times* correspondent in the Potteries has been defending the character of the manufacturers and declaring that they are really quite kind-hearted and well-meaning individuals. This is most readily admitted and has never been denied, but, like other people, they are very busy men, struggling against fierce outside competition and fighting to keep a market for their goods. They have no time to experiment; they cannot stop to think of the condition of the work-people; lead-poisoning has become such a matter of course that both work-people and manufacturers take it for granted until aroused by criticism from outside. Here and there large and wealthy firms with a scientific staff can afford to experiment and consequently obtain valuable results, but in few English industries is the English manufacturer's contempt for, and disbelief in, science more marked than in pottery manufacture.

This being the state of the case the pottery manufacturer must be stimulated. It must be made worth his while to abolish raw lead and to adopt safe frits—or, better still, leadless glazes—and this the authorities of the Home Office can do by a stroke of the pen if they like. They have only to draw up a sufficiently stringent set of rules for manufacturers using raw lead and then grant exemption from the more stringent rules (such as raising the age of workers in the dipping house to eighteen) to those manufacturers using a glaze approved by the Home Office. If the manufacturers object the House of Commons would endorse such special rules in the form of an Act. Prohibition of raw lead is a long way off, but it is easy to make it pay to abolish it, and the final blow to its use would be given by bringing lead poisoning under the Workmen's Compensation Act.

Such books as this show clearly the necessity of strong action on the part of the Home Office. Experiments are tried, results are obtained, there is much writing in newspapers and talking in Parliament, and drawing up of special rules, but the lead poisoning goes on just the same, and will go on until the Home Office takes one of two courses, either prohibits the use of raw lead or by suitable regulations makes the introduction of harmless glazes a paying affair for the manufacturer.

A Manual of Physiology with Practical Exercises. By G. N. STEWART, M.A., D.Sc., M.D. Edin., Professor of Physiology in the Western Reserve University, Cleveland. Third edition, University Series. London: Baillière, Tindall, and Cox. 1899. Pp. 848. With 5 Chromolithographs and 300 Woodcuts. Demy 8vo. Price 15*s*. net.

THE present edition of this treatise as compared with the first, which was published in 1895, is enlarged to the extent of fifty-two pages, while twenty-two woodcuts have been added. The text has been revised throughout and many small corrections have been made, whilst the well-ascertained facts which have been made out during the last three years have been intercalated. In this short period it is not to be expected that any material alteration has been required in the plan of the work, but the author has evidently taken a pleasure in keeping his knowledge up to date. Thus in the description of the chemical composition of living matter a notice of the nucleo-proteids and the proteoses or albumoses is introduced in the account of the blood, the characters of the oxyphile and basophile cells are given, and the identity of Ehrlich's neutrophile cells with the oxyphile cells of Kanthack and Hardy is pointed out, together with the proportion which these bear to each other in the blood. In human blood, says Dr. Stewart, "the finely granular oxyphile cells make up 60 to 80 per cent. of the whole number of leucocytes, the lymphocytes (and hyaline cells) 20 to 30 per cent., and the coarsely granular oxyphile cells less than 5 per cent.," though, he adds, "these proportions are far from being constant." New paragraphs are inserted dealing with the electrical conductivity of the blood and the relative volume of corpuscles and plasma in unclotted blood. The paragraphs on the coagulation of the blood have been re-written, though even yet it scarcely seems that the last word has been said in regard to it. The hypothesis here advanced, supported on recent researches, is that the presence of calcium is essential to the formation of fibrin, whilst the fibrin is formed by the union of calcium with fibrinogen (or thrombosin) under the influence of fibrin ferment (or nucleoproteid.

The author entertains no doubt about the cause of the second sound of the heart, but he speaks with hesitation of the cause or causes of the first sound, attributing that sound in part to the sudden tension of the auriculo-ventricular valves and in part to the contraction of the muscular tissu eof the heart, which he regards as being to some extent a resonance tone of the (listener's) ear. We should have thought that it was hardly worth while to revive Sir Richard Quain's theory that the first sound of the heart is due to the impact of the ventricular blood on the semilunar valves at the moment of the systole and the resistance which it encounters as it passes through the orifices of the aorta and pulmonary artery. Considerable additions have been made to the chapter on Absorption as well as to those on the Nervous System, especially in regard to its histology, and to that on the Organs of Sense. With the improvements which have been made in this edition we regard Dr. Stewart's "Manual" as one of the best works on physiology at the command of the student. It is written with great clearness and by one who is practically familiar with his subject.

A Manual of Bacteriology, Clinical and Applied. By RICHARD T. HEWLETT, M.D., M.R.C.P., D.P.H. Lond., &c., Assistant in the Bacteriological Department, British Institute of Preventive Medicine. London: J. & A. Churchill. 1898. Pp. viii., 439. Price 10*s*. 6*d*.

THE student of bacteriology has now no reason to complain of any lack of text-books; rather is he liable to be bewildered by their number and by their increasing size. It is only by a judicious selection of facts, guided by a due sense of perspective, that a writer can now hope to produce a book which will really be of practical use to the student. Dr. Hewlett has, in our opinion, achieved a marked success, and we are unable at the moment to point to any one of the smaller and less pretentious works on bacteriology which more completely fulfils the requirements of the student, especially from a practical point of view, than does the present volume. The author is actively engaged in the practical applications of bacteriology and he is not without experience in teaching the subject.

He commences with a short but sufficient account of the

Digitized by Google

structure, chemistry, and classification of bacteria, accompanying his facts with enough scientific explanation to render them intelligible. The methods of study of bacteria and bacterial diseases are given in practical detail, such selections of staining methods being described as have been found by experience useful and necessary. In describing the microscope many valuable practical hints are given, and the use of immersion lenses is illustrated by diagrams. The subject of immunity is dealt with in a not very conclusive chapter, the fault perhaps of the subject rather than of the author. The chief pathogenic organisms are described in adequate detail, commencing with the subject of suppuration and septic conditions, under which are described the pyococci proper and various other organisms having relation to sepsis. We do not find any good connected account of septicæmia—an omission which should be remedied in the next edition. Space fails us to follow the author in detail through the different sections, but the facts appear to be clearly expressed and to include the most recent information. Throughout the book those methods are given which may be most usefully employed in studying each particular organism, especially those relating to clinical examination. The bacteriology of air, water, soil, milk, &c., is dealt with in a special chapter.

The practical methods of preparing antitoxins and vaccines occupy the greater part of a useful appendix Although the grouping of pathogenic organisms in the book leaves something to be desired, and although individual statements made here and there will not command universal acceptance, yet we think Dr. Hewlett's manual is one which in its scope and method will be of great value to the student, and one, moreover, which can be taken as an accurate and safe guide both in theory and practical work.

LIBRARY TABLE.

Surgical Technics in Hospital Practice: a Handbook for House Surgeons, Students, Dressers, and others engaged in Hospital Work. By K. W. MONSARRAT, M.B., F.R.C.S. Edin., Assistant Surgeon to the Liverpool Cancer Hospital. Bristol: John Wright and Co. 1898. 8vo. Pp. 132. Price 3*s.* net.—The author tells us in his preface that this book is intended chiefly for house surgeons, and it is so essentially practical in nature that its perusal will well repay the house surgeon who is desirous of thoroughly doing his duty to the patients under his charge. Much of the success of modern surgery depends on a minute observance of many small points, and the surgeon's knowledge and skill may be all in vain unless seconded by those who have to assist him in the operation and after-treatment. The chapter devoted to personal asepsis is very good; many operators, house surgeons, and dressers are lax in cleansing their hands and some seem to imagine that a momentary dip in an antiseptic solution will suffice to render them free from germs. The best corrective for this state of mind is a course of culture experiments made from the hands after these valueless attempts at cleansing. The charge of the patient both before and after the operation is dealt with and the treatment of the chief complications which may arise after the patient is put back into bed is carefully described. Much of this information is not to be found in the ordinary text-books and therefore it is likely to prove valuable. The author advises that saline transfusion should be performed by means of a glass syringe, but the funnel and tube are certainly more convenient. One chapter describes the treatment before, during, and after the operation of "special cases," such as "operations on the brain," "operations involving the mouth and pharynx," "tracheotomy," "empyema," "abdominal section," and "intestinal obstruction." An appendix contains a code of rules for surgical nurses which might prove of value.

Injuries and Diseases of the Ear. Being reprints of papers on Otology. By MACLEOD YEARSLEY, F.R.C.S. Eng., Surgeon in Charge of the Department for Diseases of the Throat, Nose, and Ear, the Farringdon Dispensary, &c. London: The Rebman Publishing Co. 1897. Pp. 40. Price 2*s.*—The substance of this book first appeared as articles in the *Medical Times* and *Pediatrics*, though much has been rewritten. The work does not pretend to deal with the whole of the diseases of the ear, and its scope will be best indicated by quoting the headings of the six chapters which it contains; they are: "On an Artificial Membrana Tympani," "Foreign Bodies in the Ear and their Treatment," "What not to do in Diseases of the Ear," "The Use of the Pneumatic Aural Speculum," "On the Care of the Ear in Children," and "Aural Reflexes." These papers will prove useful to those who have but an elementary knowledge of the subject and therefore will appreciate the hints and cautions which the book contains.

JOURNALS AND REVIEWS.

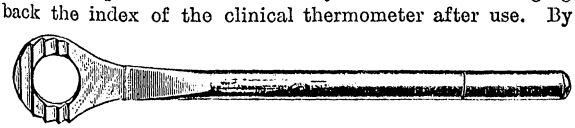
The Journal of Comparative Pathology and Therapeutics. Edited by J. MCFADYEAN, M.B., B.Sc., F.R.S. Edin. September, 1898.—This number opens with an article on the Pathology and Treatment of Spavin, translated from an article by Dr. Eberlein of Berlin which appeared first in the *Monatshefte für Praktische Thierheilkunde*. This is an admirable paper and deals very fully and lucidly with the history, pathology, and clinical treatment of spavin and similar diseases. Though all pathologists will not agree that the first change is simply an osteo-porosis there will be little doubt that most will agree as to the subsequent changes. Of course, if the meaning of the term be limited in its pathological and not in its clinical sense an agreement may be arrived at amongst pathologists, but this alone would not be of much assistance to the clinician. Professor McFadyean contributes a most valuable article on the Situation and Order of Development of the Lesions in Bovine Tuberculosis, from which it may be gathered that in cattle, at any rate, tuberculosis in the large majority of cases is contracted through infection of the bronchial and mediastinal glands, that is, through the respiratory tract. In 36 tuberculous animals a careful examination was made and one or other set of these glands was, or both were, always affected. In 5 cases the discoverable lesions were confined to the bronchial glands, in 2 cases to the mediastinal glands, and in 9 cases to the two groups of glands; 16 cases in all, or 43 per cent. of the total. In only one case were both of these groups of glands apparently healthy. The order of the occurrence of the process in more advanced tuberculosis in cattle appears to be, first, in the lungs and the pleura, then the mesenteric glands, the peritoneum, the liver, the heart and pericardium, the udder, and the uterus and ovaries, whilst the kidneys, the bones and joints, the brain and spinal cord, the spleen, the skin and the muscular systems are not nearly so frequently affected. As regards generalised tuberculosis, Professor McFadyean lays down a series of rules which will be of very great interest and assistance to those who are engaged in the examination of carcasses for tuberculosis. In an editorial article the Report of the Royal Commission on Tuberculosis is returned to and some of the salient points are brought prominently forward, especially those relating to the prophylaxis of tuberculosis. "Some Abdominal and Uterine Operations in the Dog and Cat" are recorded by Professor F. Hobday, who, summing up his cases of abdominal and uterine surgery, states that "the abdomen of the dog and cat can be opened without any great dread of the consequences, although of course no one should treat carelessly any operation involving laparotomy. With strict attention to asepsis, thanks to the researches of Lister, the surgeon

Digitized by Google

nowadays need not dread interfering with the peritoneal cavity whenever that may be considered absolutely necessary." Reviews and the report of the opening meeting of the Royal Veterinary College, London, make up the number.

Scottish Medical and Surgical Journal.—Dr. Alexander Bruce (Edinburgh) writes on the Origin of the Facial Nerve. He considers that it has a crossed root which does not arise from the opposite facial nucleus but can be traced in an upward direction through the posterior longitudinal fasciculus, and is probably concerned in the innervation of the upper facial muscles. Dr. Robert Jardine (Glasgow) gives notes of four cases of Cæsarean Section. Dr. McVicar (Dundee) describes a case of Visual Aphasia and Amnesia Verbalis.

Edinburgh Medical Journal.—Dr. H. W. G. Mackenzie and Dr. W. E. Dixon discuss the action and properties of podophyllin. They have found that the Indian podophyllin is nearly twice as physiologically effective as the American. Dr. G. A. Gibson writes on Paralysis of the Sixth and Seventh Cranial Nerves. Dr. Alexander Morison has a short paper on the Innervation of Intracranial Vessels. Dr. A. A. Warden (Paris) describes a successful case of Internal Urethrotomy with Maisonneuve's instrument.

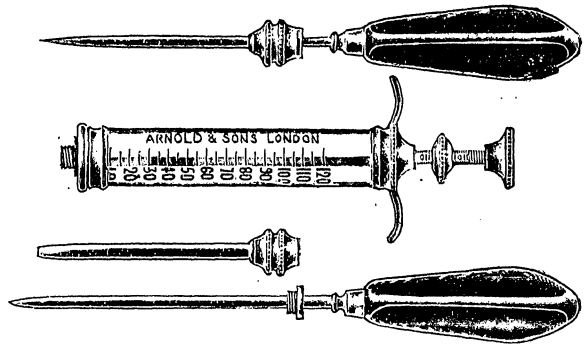


Dublin Journal of Medical Science.—The original articles are on the Treatment of Tetanus with Antitoxic Serum, by Mr. R. G. Patteson; on the Relations between Preventive Medicine and Vital Statistics, by Dr. T. W. Grimshaw, C.B., Registrar-General for Ireland; and a Medico-Statistical Sketch of the North-West Frontier Disturbances in India, by Surgeon-General A. A. Gore.

Écho du Bien.—The October number has two articles on Hospital Abuse, one by Dr. Variot of the Hôpital Trousseau, whose refusal to give gratuitous advice to well-to-do out-patients has recently attracted much attention to this question in Paris and has already been referred to by our Paris Correspondent in THE LANCET of Oct. 8th and 15th. Dr. Variot refers in terms of approval to the objects of the Hospital Reform Association in this country.

New Inventions.

A COMBINED TONGUE DEPRESSOR AND THERMOMETER CASE.

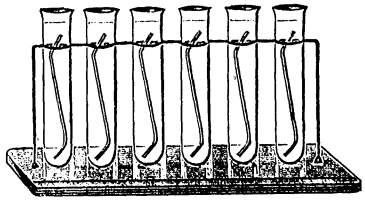


THIS useful combination, designed by Mr. J. B. Gabe of Swansea, is very compact and combines the two articles in the space and at the price of one. One advantage which this instrument possesses is the facility it affords for bringing back the index of the clinical thermometer after use. By

placing the thermometer in the case bulb upwards the index may be shaken down without any danger of breakage and with little or no trouble, the tongue depressor forming a handle for this purpose. The price is 2*s.* 6*d.*, and the manufacturers are Messrs. Lynch and Co., Ltd., Aldersgate-street, E.C.

HYDROCELE INJECTION APPARATUS.

MESSRS. ARNOLD AND SONS, of West Smithfield, London, have manufactured, at the suggestion of Dr. Cuthbert Bowen, of Bridgetown, Barbados, West Indies, a hydrocele injection apparatus which possesses several distinctive qualities. The barrel is graduated with clear black markings so that the exact amount of fluid drawn up is indicated, and the piston rod is similarly graduated and provided with a sliding stop ratchet, thus preventing the injection of more iodine or bichloride of mercury solution than is intended. The cannula screws on firmly by threads to the syringe, so that none of the injection fluid can be lost and the surgeon's fingers cannot come into contact with the iodine. The special feature of the instrument, however, lies in the fact of the trocar screwing into the cannula and becoming incorporated with it. When the point of the trocar protrudes to the extent regulated by the threads it will be found that the trocar and cannula are invisibly merged one



The upper figure shows the trocar in the cannula, the next the syringe, and the two lowest figures the cannula and trocar separately.

in the other, and on running the finger up and down the outside of the instrument there is an entire absence of collar. After having been in use for some time cannulas of ordinary make hang loosely on their trocars and the patient experiences discomfort during the injection, but in Dr. Cuthbert Bowen's apparatus the cannula and trocar together form an apparently solid needle which causes the patient hardly any pain in its introduction. The projecting horns on the syringe enable the operator to work it with one hand, leaving the other free for the manipulation of the part to be injected.

AN ASEPTIC FEMALE CATHETER STAND.

MESSRS. REYNOLDS AND BRANSON, Ltd., of 13, Briggate, Leeds, have submitted to us an aseptic stand which they have specially designed for use in female hospital wards. It consists of a heavy plate-glass slab with rounded corners,

having a half-inch frosted strip running along the whole length of it, upon which the patient's name may be easily written with a pencil. The ringed support for holding the six strong glass test-tubes is made of metal thickly tinned, so that the whole apparatus is quite aseptic. The test-tubes can either be used to hold the fluids necessary to asepticise the glass catheters or as specimen glasses for urine. By the way, glass catheters do not commend themselves to the majority of surgeons, and the risk of accident in their use, however remote, must not be forgotten.

FOOTBALL FATALITIES.—A young man, aged nineteen years, of Farnworth, near Bolton, who was injured while playing for a Walkden football club in a match on Nov. 5th, died on the following Wednesday. He collided with another player, whose knee struck him in the abdomen.—A young man, aged twenty-four years, while playing a game on Nov. 10th, sustained injuries to the abdomen from which he died on the following Sunday, an operation proving futile to save him.—In a match at Association rules between Dewsbury and Sheffield at Dewsbury on Nov. 12th, the visitors' centre forward, a young man, aged twenty years, died on the ground. He was struck by the ball in the abdomen and fell, after continuing to dribble for some 20 yards. A medical man was playing in the match so that the deceased received medical attention at once. All efforts were without avail and death ensued in a few minutes. The body was subsequently removed to the Dewsbury and District Infirmary.

THE LANCET.

LONDON: SATURDAY, NOVEMBER 19, 1898.

THE General Medical Council will meet at two o'clock on Tuesday next and it is not very difficult to make a forecast of its discussions and work. The Council has a bad habit of putting off to the last hours of its session some of the most important subjects, leaving them as a legacy for the next session and, like another Parliament that might be mentioned, of grappling with too many topics at once, a method of procedure which leads to an endless waste of time. As we read the proceedings of the last meeting of the Council and of the Executive Committee as contained in the respective minutes of the two bodies, we can with much confidence anticipate that most of the following subjects will again engage the attention of the Council: the memoranda of the Council on the reciprocity of practice between this and foreign and colonial countries; the features essential to any workable Midwives Bill; the disciplinary powers of the diploma- and degree-granting bodies; the efficiency of the examinations of the Apothecaries' Hall of Ireland; the raising of the standard of the preliminary examinations recognised by the General Medical Council; and the extension of the rule against the employment of unqualified assistants to dentists. This is a sufficient programme to occupy the Council for several days. But it is far from complete. It does not include penal cases, which generally occupy two days of the Council's time; nor does it include a very sweeping proposal by Mr. GEORGE BROWN to disestablish all the committees and relegate the work of all of them to the branch councils, or another by the same member to add to the number of Direct Representatives in consideration of the large increase in the number of practitioners on the Medical Register. Finally, the programme takes no notice of questions which were settled, in a way, at the last meeting of the Council but which may be found to have been rather too vaguely disposed of. Nor does it provide for reports of such committees as that appointed at the last meeting to take such steps as were deemed most effective to induce the Government to insert a clause in the Companies Act Amendment Bill in order to prevent the registration of companies formed to carry on medical, surgical, and dental work.

It will be generally admitted that the most important subject in the above list is the proposal to raise the standard of preliminary education by revising the list of preliminary examinations now recognised by the General Medical Council. Already the action of the Council on this subject has been challenged, and so challenged that it had to defer the operation of its resolution of Nov. 29th, 1897, to bring a revised list into force on Jan. 1st, 1899. The notice given under this resolution was thought to be too short, especially as some of the bodies affected by it, notably the College of Preceptors, felt aggrieved. It is of great moment that this sense of grievance should be removed, and of still more moment that the question of standard should be settled. There is a universal consensus of opinion in favour of raising the standard of general education. This consensus embraces educational authorities both in and out of the profession. The supply of students is so plentiful, and the general means of education so improved, that the experiment can be made with safety. Under these circumstances it may be hoped that the General Medical Council will give its best and its early attention to this subject and settle it boldly, without favour or fear.

The next most pressing subject in the above list is that of the disciplinary powers of the various diploma- and degree-granting bodies. The entire want of the most obvious and elementary powers in some of these, notably in certain of the universities, leads to the scandal of persons who have been convicted of felony and whose names have been removed from the Medical Register still continuing in full possession of their status and titles as graduates of ancient universities. Some bodies have the power of removing from their rolls the names of their members without any corresponding power of restoring them; hence the reluctance to inflict necessary punishment when the punishment cannot be graduated in proportion to the offence. The General Medical Council itself often removes names with the intention of restoring them; at any rate, it often does restore them. It would be as absurd to remove some names from the Register without the possibility of their being re-instated as it would be to pass sentence of capital punishment in cases of minor offences. The lawyers of the Council have expressed the strongest opinions as to the necessity for some legislation for the removal of these evils, and at the last meeting of the General Medical Council the President was requested to put himself into communication with the Lord President of the Council in reference to this subject. We shall hear how far such communications have been successful. The present state of the law makes the Bodies represented on the General Medical Council ineffective in maintaining the full discipline of a profession in which the public itself has such a great interest. It is not to be expected that the Government will undertake such legislation *proprio motu*. It has too much to do in other directions. But the need for such legislation is obvious. If the Council can convince the Government that it and the qualifying bodies are in earnest in asking for such powers doubtless the Government will find ways of bringing in a Bill for the purpose.

IF Italy is the recruiting ground of the political assassin she is also the parent of the "criminal anthropologist," and rightly so. Given a CASERIO and a LUCCHENI, we have as a scientific aftergrowth a LOMBROSO and a FERRI—the bane, as in the universal economy of nature, evoking its antidote. The fact is one to be remembered and duly weighed by those whose attitude towards the subalpine professor and his school is too critical to be cordial. "Put yourselves in our place," say LOMBROSO and his disciples, "and you will look with tolerance, not to say benevolence, on our studies." This argument *ad hominem* is as justifiable as such arguments can possibly

Digitized by Google

be. Italy, as criminal statistics amply attest, exceeds all Europe put together (minus the Iberian peninsula) in the number of her homicides. As her able statistician, Baron GAROFALO, words it: "She commits a murder every two hours." Not only so, but she lends herself as the prompt and effective tool for homicidal purposes abroad. Of the three anarchist assassinations perpetrated in Europe within as many years all of them were the work of Italians. Italian, moreover, was the nationality of the miscreants who on the eve of the Emperor WILLIAM'S visit to Palestine were by the vigilance of an English official arrested at Alessandria when plotting against His Majesty's life. By none are such facts more freely admitted and more poignantly deplored than by right-minded Italians themselves—so much so, indeed, that the working men of Rome have formed a league *contro il coltello*, to disarm their fellows of the homicide's favourite, because all too handy, weapon. What wonder in these circumstances if patriots, as well as nature-students like LOMBROSO and his school, should endeavour to go a step deeper and in addition to impounding the knife seek to improve the men who wield it?

"It is for this reason we are criminal anthropologists," says the Turin professor, and none who wish well to Italy but must applaud his inspiration, even while doubtful as to the scientific basis of his methods. But are these methods so unsound as certain extravagances in their tenour or over-confidence in their pretensions seem to indicate? They are neither more nor less than an adaptation to modern conditions, in the light of a profounder, more refined physiology, of what the brothers COMBE, of Edinburgh, some eighty years ago imported from Germany; they proceed from a practical recognition of the truth that character is largely, if not wholly, conditioned by organisation, and that this in turn is largely, if not wholly, conditioned by inheritance and environment, physical and moral. Take the child, says LOMBROSO, at the earliest stage possible, above all before coming into contact with other children at school, and let him undergo the thorough examination, "anthropometric and psychiatric," which can detect abnormalities, congenital and other, at a stage when they can be remedied or removed. From such an examination his up-bringing should start, and according to its findings he should be allowed to associate with his fellows or be segregated from them till such time as his defects are overcome. Had this procedure been carried out in the case of ninety-nine-hundredths of her criminals and assassins Italy would now be witnessing a depletion of her engorged prisons and penitentiaries and, instead of being in imminent danger of becoming an international pariah, would have seen her immigrants welcomed by the most normally developed of the sister powers as a special force in domestic progress and in common evolution. Now, however, her capital is shortly to be the appropriate seat of a Congress to devise means for counteracting a "diseased development" of which she supplies the most typical exemplars—a development which reached its sinister culmination in the *belva umana* (the human wild beast), as she calls him, who has just been sentenced at Geneva.

Scarcely had the tragic death of the Austrian Empress become known, when LOMBROSO began to collect information as to its author with a view to confirm the "family likeness" common to all such miscreants and once more drive home the moral it carries to an all too apathetic Government. Every reminiscence of LUCCHENI'S parentage, youth, and occupation which could be extracted from companions and employers LOMBROSO has laid under contribution, and he has supplemented the whole by as copious an assortment of specimens of the man's handwriting and photographs from time to time taken of him as he could amass. On these materials he has lavished the professional acuteness and the vast personal experience in criminal developments which he is known to possess and the result is before us in an elaborate paper—"LUCCHENI giudicato dal punto di vista antropologico-psichiatrico" ("LUCCHENI judged from the anthropo-psychiatric point of view"). A careful and keenly analytical narrative of the man's illegitimate origin from a dipsomaniac father, of his abandonment when yet of tender years in one of those *ricoveri* which are simply "criminal forcing-houses or preserves," of his early addiction to lying whenever an abnormal vanity prompted it, and of the instability of character thus fostered in one not wholly vicious or even unamiable, leads up to a detailed anthropometric and psychiatric examination in which practice aiding personal aptitude has made LOMBROSO a master. The organic nexus between the traits, intellectual and moral, and the development, cranial and corporeal, is lucidly indicated, until the diagnosis seems fairly established that we have to deal with a "brachycephalous epileptic," in whom, "as in primitive man and as in the typical anarchist, crime is confounded with action"—the natural expression of an "absolute want of the moral sense." Then follows an example of LOMBROSO at his best in a comparison of the calligraphy of LUCCHENI not only with that of other criminals but with LUCCHENI'S own at different stages of his career—a curious and significant resemblance being noted between his handwriting and that of CASERIO immediately before he murdered President CARNOT and also that of the assassin of General ROCHA. In these LOMBROSO finds evidences of a "double personality," further indicated by the man's mental revelations—a *doppia personalità* explaining and reconciling certain contradictions in his life and his actions which the mere forensic pleader is apt to insist upon in abatement of guilt or as disproving innocence. This double personality he has found in nearly all such *belve umane* capable of proceeding without apparent motive from the gentlest dealing to the most ruthless ferocity, dominated by an *impulsività* hysterical or epileptic, betrayed even in the unstable handwriting which alternates between the *macrografia* (large calligraphy) and *microgrāfia* (small calligraphy) characteristic of them.

Leaving LUCCHENI to be dealt with by the judicial tribunal, "according to its lights" and "in conformity with legal precedent," LOMBROSO appeals once more to his Government for a reform in education which would minimise the production of such diseased developments or in good time save society from the contamination or the risks which their unrestrained intercourse with it must incur. Into this part of his exposition we cannot enter. Such a vast rehabilitation of her system of public instruction as he demands would imply on Italy's part a political

Digitized by Google

and administrative transformation for which she has long to wait. Meanwhile she can do something towards relieving her "bloated armaments" of their plethora and correcting thereby the anæmia of her primary schools. She has as Education Minister a large-minded and accomplished medical man, well known to be in sympathy with the propagation of the subalpine school. It will be disappointing if another change of Cabinet brings about that "solution of continuity" which has proved fatal to much of her best legislation—to none more than to that repeatedly introduced for scholastic and university reform by his Excellency Dr. BACCELLI. But perhaps the International Congress about to meet in Rome will end by infusing better counsels into her Parliament and restoring her to her healthier and nobler personality in which the CASERIOS and LUCCHENIS, actual and potential, will have ceased to be more than exceptional phenomena.

THE liberty of the press is dear to our hearts, and by liberty we do not mean licence. But a recent trial at the Central Criminal Court would seem to show that the law finds it as difficult a task as less instructed folk to distinguish where the one begins or the other ends. The facts of the case to which we refer will be remembered. GEORGE BEDBOROUGH, a publisher, was charged with publishing and selling certain obscene literature. He pleaded guilty on three counts, the first relating to a book, the second to a lecture, and the third to a magazine. With the last two counts we have nothing to do, but on the charge concerning the book we purpose to speak and we make a somewhat lengthy reference to the matter because of its great importance to medical and scientific authors. The Recorder, after the formal plea of guilty had been entered, said that the defendant had acted wisely in pleading guilty to the three counts, for it would be impossible to persuade anybody that the book, magazine, and lecture were not obscene works. While he was willing to believe that the defendant might at the outset have been gulled into the idea that some might call the book a scientific work, it was impossible for anyone of ordinary judgment not to see that to be a sham. As the defendant had taken only a very small part in the matter the Recorder did not consider it right that he should suffer while others much more guilty went scot free. But the publication of indecent literature must be put down by the strong arm of the law. So he bound the defendant over in his own recognisances in £100 to come up for judgment if called upon.

Now, the result of this trial places the person or persons to whom in the Recorder's opinion greater blame should be attached in a very awkward position. There is, for example, the author of the book. The trial closes his mouth and prevents him from making any defence other than the unsatisfactory method of writing to the newspapers or publishing an Apologia, and Mr. HAVELOCK ELLIS, the writer in question, would seem to be obviously indicated in the Recorder's speech. His book is the first of a series of studies in the psychology of sex and deals with a phase of the question which we must all admit to exist—namely, sexual inversion. It is allowed that this subject touches the very lowest depths to which humanity has fallen. But for all that it is a subject which cannot be ignored and one which is not made any less powerful for ill by the pretence that there is no such thing. But while we admit that the subject of sexual inversion has its proper claims for discussion we are very clear as to the propriety of limiting that discussion to persons of particular attainments. When Mr. HAVELOCK ELLIS'S book was sent to us for review we did not review it, and our reason for this neglect of the work of the Editor of the "Contemporary Science Series" was not connected with its theme or wholly with the manner of its presentment. Mr. HAVELOCK ELLIS'S book is written in a purely dispassionate and scientific style and the only exception we take to the treatment is that we consider some of his quotations unnecessary because a scientific public is already familiar with the originals, and some of them useless, being drawn from tainted sources. We may say also that we do not agree with his view of the question, for we consider that such matters are far better treated from the psycho-pathological standpoint of KRAFT-EBBING than from that of ULRICHS, with whose theory as to the naturalness of homo-sexuality Mr. HAVELOCK ELLIS seems in agreement; but a difference of opinion would not have prevented us from giving publicity to the author's labours. What decided us not to notice the book was its method of publication. Why was it not published through a house able to take proper measures for introducing it as a scientific book to a scientific audience? And for other reasons, which it would serve no purpose to particularise, we considered the circumstances attendant upon its issue suspicious. We believed that the book would fall into the hands of readers totally unable to derive benefit from it as a work of science and very ready to draw evil lessons from its necessarily disgusting passages. It must be pointed out, too, that a more than ordinary danger is attached to Mr. HAVELOCK ELLIS'S work as a book for laymen in that the author's views happen to be that sexual inversion is far more prevalent than we believe it to be and that the legislature does injustice to many by regarding as crimes the practices with which it is bound up. He has failed to convince us on these points; and his historical references and the "human documents" with which he has been furnished will, we think, fail equally to convince medical men that homo-sexuality is anything else than an acquired and depraved manifestation of the sexual passion; but, be that as it may, it is especially important that such matters should not be discussed by the man in the street, not to mention the boy and girl in the street.

What constitutes indecent literature? Is a book indecent because it deals with an indecent subject? Surely there is no reasonable person who will say "Yes." A book written solely in a spirit of scientific inquiry into a subject which, though odious in itself, has yet to be faced cannot possibly be included under the head of indecent literature. But such a book may become indecent if offered for sale to the general public with a wrong motive. BEDBOROUGH was, we suppose, held by the Recorder to be guiltless of wrong motive or he would have been punished. But why this wrong motive should be imputed to the author we cannot guess; while if no such imputation was intended the reference

Digitized by Google

to the more guilty persons who went scot free is meaningless. Mr. HAVELOCK ELLIS seems to us to have been badly treated in the matter and unfortunate in his publisher, for BEDBOROUGH, it must be remembered, pleaded guilty to the issue of two other indecent works with which the author of "Sexual Inversion" had no connexion whatever. The moral of the story for scientific writers, who must often publish what would be obscene if appearing in doubtful channels or confided to dirty hands, is obvious. It is—be careful about the publisher.

Annotations.

"Ne quid nimis."

THE SOUDAN GAZETTE.

WE heartily congratulate all, of whatever service and rank in that service, whose names compose this week the list of honours in recognition of services in Egypt during the recent military operations. We also congratulate the authorities upon their promptitude in awarding these honours. Among the names occur those of twelve officers of the Royal Army Medical Corps. Surgeon-General William Taylor and Colonel W. H. Macnamara receive the Companionship of the Order of the Bath; Lieutenant-Colonel G. A. Hughes, Major E. M. Wilson, Major H. B. Mathias, and Captain C. S. Spong receive the Distinguished Service Order; Lieutenant-Colonel T. J. Gallwey, C.B., Principal Medical Officer of the Egyptian Army receives brevet rank as full Colonel; Major G. W. Robinson receives brevet rank as Lieutenant-Colonel; Captain R. H. Penton, D.S.O., and Captain H. E. H. Smith receive brevet rank as Majors; Lieutenant E. W. Bliss receives brevet rank as Captain; and Lieutenant-Colonel A. T. Sloggett is granted the next higher rate of pay to his rank. The medal for Distinguished Conduct in the Field has been granted to 5 non-commissioned officers and 1 private of the Royal Army Medical Corps—viz., to First-class Staff-Sergeant Hoist, Sergeant F. Crooke, Sergeant G. A. Benson, Sergeant Scrase, Lance-Sergeant A. P. Mears, and Private A. Davidson. We also record with pleasure that Veterinary-Captain L. J. Blenkinsop receives the Distinguished Service Order, Veterinary-Lieutenant T. E. W. Lewis the brevet rank of Veterinary-Captain, and Veterinary-Captain G. R. Griffith, D.S.O., the next higher rate of pay of his rank; and that the decoration of the Royal Red Cross has been conferred upon Miss S. E. Webb and Miss A. F. Grist of the Army Nursing Service, and Miss E. Geddes of the National Society for Aid to the Sick and Wounded in War. No medical man receives on this occasion the much-coveted Victoria Cross, which is so rightly bestowed upon Captain P. A. Kenna, Lieutenant the Honourable R. H. L. J. de Montmorency, and Private Thomas Byrne, of the 21st Lancers, for gallant behaviour during the famous charge of that regiment; and upon Captain N. M. Smyth, of the 2nd Dragoons Guards for saving the life of a camp-follower at imminent risk to himself during the battle of Khartoum.

LAY CRITICISM OF MEDICAL AFFAIRS.

WHEN the man in the street criticises some isolated incident in which questions scientific or technical alone are involved he is apt to do so by the light of his necessary ignorance, so that he falls inevitably into error and unintentionally into injustice. Similarly the writer for the lay press, who is often but the man in the street with the practised habit of ready writing, is apt not only to be wrong himself but also to mislead others. The same, however, cannot always be said in the occasional cases in which wider interests are involved, in which the public good is at stake, and in which, although scientific knowledge may be necessary in order to fully appreciate them, there is a side of the question not exclusively professional or of which the scientific aspects are capable of being grasped by anyone bringing an intelligent mind to bear upon them. We need not say that the British public is anxious to form correct opinions and to form them honestly, while the British press is, as a rule, anxious to guide it according to its lights upon the right path. On the question of vaccination, for example, valuable support has recently been received by the medical profession from the healthy common-sense and sound criticism brought to bear upon it by the more important part of both press and public. On such questions it is sometimes easier for laymen to give open expression to their opinions than it is for medical men, as they at least cannot be said to be actuated by a bogey known as professional jealousy or prejudice. This, perhaps, is why the criticism recently accorded by an evening contemporary to the society fad known as "Christian Science" has proved of considerable value to the public. The articles, published some weeks ago, have been reprinted in the *Westminster Budget* and are instructive reading. The most stringent form, however, of lay criticism, that which can least easily be ignored and the results of which are most widely known, is to be found in our courts of law. To this, as the result of a recent inquest, which we noted in THE LANCET of Nov. 12th, "Christian Science" is now to be submitted in the person of a lady professing to heal by its means in return for a monetary consideration, and of another upon whom lay, in the opinion of a coroner's jury, the duty of summoning medical aid to a sick man. The danger of coming into collision with the law for the deliberate and intentional neglect of duty towards the sick and helpless has hitherto been demonstrated by cases where the sect known as the Peculiar People have allowed their children to die rather than call in medical aid, a gruesome test of faith to which apparently no "Christian Scientists" have hitherto in this country submitted themselves.

THE FATAL GLOVE FIGHT.

MR. TROUTBECK, the coroner for Westminster, held an inquiry on Nov. 14th into the circumstances attending the death of Thomas Turner, aged twenty-three years, who died on Nov. 10th in Charing-cross Hospital after engaging in a glove fight at the National Sporting Club on Nov. 7th. The fight was "a match of twenty rounds at 8 st. 8 lb. with 4 oz. gloves." Actually 5 oz. gloves were used. The referee gave evidence that the fight was in no way a severe one. The men were very evenly matched and during the thirteenth round Turner received a light blow on the side of the head close to the right eye but some inches away from the "point." He then collapsed and the referee stopped the fight. After some brandy had been administered he revived, stood up, shook hands with his opponent, sat down again, and became unconscious. Mr. Jackson Lang, who was present as a spectator, said that he attended Turner, who showed symptoms of extreme collapse and inequality of his pupils. Mr. Malcolm Smith, who made the post-mortem examination, said that Turner's heart was extremely weak and small. On the right side of the brain was a clot of blood. The jury returned a verdict of "Accidental death," with a rider suggesting that the club should

Digitized by Google

instruct a medical man to examine the physical condition of candidates for boxing competitions before allowing them to take part in any fight. Turner, it appears, had not undergone any medical examination before fighting, but even if he had we are not certain whether any medical man could have certified him as unfit. We doubt whether the diminution in the normal size of the heart could have been diagnosed, and if it had been, a small heart need not necessarily mean an unhealthy heart. However, there can be no harm in the National Sporting Club adopting the suggestion of the jury, but this particular accident appears to us to have been unavoidable.

INSTRUCTION IN TROPICAL MEDICINE.

IT is now generally known that at the instigation of Mr. Chamberlain it is proposed to establish an institution for the teaching of tropical medicine. A circular has been sent from the Colonial Office to the medical schools in reference to the matter, the essence of which is the following. In a previous letter it had been stated that Mr. Chamberlain had been endeavouring to make arrangements for giving to colonial medical officers special clinical instruction in tropical medicine, such as is given at Netley and Haslar in the case of medical officers of the Army, Navy, and Indian Medical Services, for from lack of the necessary material this tuition cannot be given in a satisfactory manner at the medical schools. Such arrangements have now been made. "The directors of the Seamen's Hospital at the Albert Docks, which offers exceptional opportunities for studying cases of tropical disease, are providing the necessary buildings and teachers for the accommodation and instruction of the medical officers who may hereafter be selected by the Foreign Office and the Colonial Office for appointments in the tropics. A substantial contribution towards the initial cost of the buildings is being made by the Government, and it is hoped that by Oct. 1st, 1899, it will be possible to receive medical officers at the hospital for purposes of instruction." It is proposed that, as is at present the case, candidates for medical appointments in the British colonial possessions shall be fully qualified before they can be put upon the Secretary of State's list; that from this list a certain number shall be elected annually to fill the vacancies which may occur in the colonial medical service; that the selected candidates shall be trained for a period of at least two months at the Seamen's Hospital; and that they shall then be sent to the colonies or protectorates to which they have been allotted, where, when practicable, they will be attached in the first instance to the headquarters hospital for the purpose of gaining additional experience. The circular goes on to state that although the school at the Seamen's Hospital is designed for the training of medical officers for the Government service, doubtless there will be many other medical men, such as the medical officers of missionary societies and trading corporations and private practitioners who propose to settle in tropical countries, who will be glad to avail themselves of the advantages which such a school can offer. The colonies are being asked to make pecuniary contributions, to collect pathological material for use in the school, and to support the scheme in every possible way. The Royal Society has nominated two competent observers to proceed to Italy and then to Africa to study the subject of tropical malaria, and in addition the Secretary of State for the Colonies has nominated an experienced medical officer of the Colonial Service to aid in the investigations. Such, then, are the main features of the scheme for special instruction in tropical medicine. All members of the medical profession will support Mr. Chamberlain in his endeavours to increase the facilities for the teaching of that branch of medicine which is so important for the welfare of Englishmen residing in tropical countries, but we doubt whether the opinion will be so unanimous as to the suggested methods in the circular of which we have given an abstract. Our naval and army surgeons have not suffered in this respect, for the teaching at Haslar and Netley is of the very best, and at the latter place there are more cases of tropical disease than are to be found in any other hospital in Europe. At nearly all the medical schools, also, courses of lectures on tropical medicine have been delivered by medical men well qualified by experience to do so, but practical teaching, which of course is essential, has been lacking. The question therefore arises, Is the selection of the branch hospital of the Seamen's Hospital at Albert Docks a wise one? There are many objections—for instance, the size of the hospital, the difficulties of access, and the depletion of the old parent hospital at Greenwich of its most interesting material. And then arises the all important question—Are the cases of tropical diseases met with at this hospital sufficiently numerous to justify its selection as a school for the teaching and investigation of such diseases? Full details on this point would be valuable. We may refer to one disease most commonly met with in the tropics—namely, hepatic abscess. In twenty-five years at this hospital and its branch at the docks only 50 cases have been so diagnosed, and it is, of course, open to doubt how many of these were cases of ordinary subphrenic abscess. It would be profitable before any large sum of money is laid out to compare such statistics with those of other hospitals, notably those of Haslar and Netley, the London Hospital, and Guy's Hospital, in order to satisfy the minds of all as to the wisdom of selecting the branch hospital at Albert Docks for the very excellent purpose designed by Mr. Chamberlain. The proposed school is estimated to cost £13,000 to build and equip and £3000 annually to maintain. Of the £13,000 the Colonial Office will contribute £3500. The remaining £9500 it is proposed to levy from the British public, colonists, and Indian subjects. But no information is at hand as to the source of the annual £3000. If it be necessary that tropical medicine should have a school all to itself in London, why should it be placed so far away? The *Dreadnought* is much nearer and with its 235 beds is more capable of affording clinical material than is its branch with its present 18 and proposed 45 beds.

A CASE OF TYPHUS FEVER IN SOUTHWARK.

A REPORT on a recent case of typhus fever was read by Dr. F. J. Waldo, medical officer of health, to the vestry of St. George, Southwark, on Tuesday evening last. The facts of the case were simple. A young man, aged nineteen years, a brushmaker, resident in the parish of St. George the Martyr, was admitted to Guy's Hospital, where he developed what was recognised to be an attack of typhus fever. Dr. Waldo, when notified of the occurrence, at once took steps for the thorough disinfection of the patient's dwelling and its contents. The house consisted of two rooms, inhabited by a family of six persons, father, mother, and four children, of ages ranging from nineteen to ten years, who all slept in a single upstairs bedroom. Of the inmates who had been exposed to the infection four were at once removed to the recently established reception house belonging to the parish, and two days later the fifth entered the same place, where they and their belongings were disinfected. They remained in the reception house upwards of 14 days. The special precautions taken consisted in burning bedding and clothes and in disinfecting and cleansing the rooms at the cost of the vestry, together with the isolation of the persons exposed to infection above

Digitized by Google

referred to, and in view of the highly infectious nature of typhus fever it is satisfactory to note that no spread of the disease has hitherto occurred. From a careful consideration of the facts Dr. Waldo concluded that the case, if not actually contracted from disease germs latent in the house, was certainly rendered more dangerous by the crowded condition as to space both of the house and of the neighbourhood, and pointed out that powers were already in existence in Part III. of the Housing of the Working Classes Act, 1890, whereby the London County Council as local authority under the Act might provide dwellings for the working classes, the intention of the Act appearing to be the relief of overcrowding in poor districts. Dr. Waldo is to be congratulated upon his expressed intention of following the matter up, and we may add that in all large urban districts medical officers of health will do well to be on the alert against typhus fever, which, though a rare disease in England, is not obsolete. The sad little epidemic of last year in North Kensington would prove this, even if reports of recent cases in Islington, Kensington, and Southwark did not arouse apprehension.

AN INFANT'S STARVATION DIETARY.

WE learn that the Hackney vestry have distributed at the instance of their medical officer of health a circular throughout the district warning all parents and guardians of the real nature of "condensed separated" and "condensed skimmed" milks. It cannot be too widely known that these preparations are utterly incapable of supplying those food elements which are essential for the proper nourishment and growth of the body of an infant. At their best these preparations are but a concentrated nitrogenous and sugary food which is calculated to overtax the digestive organs of the infant, affording no nutrition, and probably leading to exhaustion. It is monstrous, we think, that there is apparently the necessity of issuing such a warning. There is no doubt that thousands of poor mothers buy this stuff under the delusion that it is an efficient substitute for natural milk. Instead of the issue of a warning of this sort we should like to see the sale of milk thus denuded and otherwise fabricated prohibited altogether or else the tins compulsorily labelled in bold and striking letters to the effect that in no case should the contents be regarded as taking the place of the natural article.

THE CERTIFYING OF WORKHOUSE LUNATICS.

A CORRESPONDENT writes to us as follows:—"As medical officer to the workhouse I informed the relieving officer that a patient there required removal on account of insanity. The magistrate to whom the relieving officer applied called in another surgeon who certified the insanity. This is a new departure here, pauper cases having been previously certified as a matter of course by the medical officer." The point raised by our correspondent is one which is not infrequently raised by medical officers of workhouses, and the solution of it not infrequently gives some trouble to boards of guardians. Like most questions of this sort it has two distinct aspects from which it may be viewed—a legal and a common-sense point of view. From a legal point of view the medical officer of the workhouse is powerless to do anything in the matter referred to. The Lunacy Act places absolute discretion in the hands of the justice whom he shall summon to his aid to investigate a case of lunacy concerning which he has received notice in due form from the relieving officer, constable, or overseer of the parish. Nor can the board of guardians or the relieving officer do anything in the matter, if the justice has a fancy for one particular medical man. It is true that the relieving officer sometimes ventures to remark, when he takes his notice, as he usually does, in person to the justice, that "Dr. A. is out of town," or that "Dr. B. has had this particular case under his observation," but he renders himself liable to be told to confine his attention to his own duties. Turning now to the common-sense view, there is much to be said in favour of the medical officer of the workhouse being selected by the magistrate to examine and certify in cases of alleged lunacy brought into the workhouse. No one is so likely to be possessed of all the facts of the case as he is, and no one knows better whether the case is a suitable one for a lunatic asylum, an imbecile asylum, or to be discharged, as the medical officer who has been watching the patient from day to day and who sent the notice to the relieving officer concerning the case. Indeed, in many parishes there is a semi-official agreement (we say "semi-official" because the discretion is so absolutely in the hands of the justice under the Lunacy Act that no agreement can override it) between the guardians and the medical officer of the workhouse, the justice concurring, that the medical officer shall certify in all cases which pass through the workhouse at a fixed fee. But, on the other hand, it is alleged, though we cannot for one moment admit the truth of the suggestion, that an arrangement of this sort is liable to abuse by the medical officer of the workhouse sending notices about cases unnecessarily. Even in cases where it may appear unnecessary it is desirable in doubtful cases that the justice should have an opportunity of examining the case and either discharging or certifying for the removal. Many alcoholic cases present considerable difficulty as to a diagnosis of lunacy and they should always be certified in due form, after consultation between the medical officer and the justice. As well might it be alleged that the justice in summoning a medical man to examine an alleged lunatic of whom he has received information from the relieving officer is guided by personal considerations (it has been alleged, for instance, that a justice thus rewards his family medical attendant) in preference to those of the practitioner's suitability and knowledge of lunacy. In reference to the special case of our correspondent he can do nothing but discuss the matter amicably when occasion offers with the more influential of the guardians and in that way endeavour to induce the justice to acquiesce in some such arrangement as that indicated above.

A JEW'S OBJECTION TO SERVE ON A CORONER'S JURY.

IN THE LANCET of Nov. 12th (p. 1282) we mentioned that a difficulty had arisen in Manchester with regard to viewing the body when a Jew was summoned on a coroner's jury. On Nov. 14th, in the same city, two Jews were summoned—one for the sixth, the other for the second time—to serve on the city coroner's jury, and, as before, they objected to do so on the ground that viewing the body was opposed to their religious convictions and that it was against the Jewish law. The coroner said it would simply make them "unclean" for a certain period. One of the objectors is reported to have said that he "was no Biblical scholar, but a conscientious believer in the Jewish law." The coroner said that if they were made unclean they could not give the blessing in the synagogue for seven days. It was an unpleasant duty to view the body, but they ought to do their duty as citizens, and he asked what reason there was why they should not be unclean? Unfortunately one of the objectors gave it out when the summons was served that he was in London when it was known that he was in Manchester and he was asked if telling an untruth made him unclean. Some elements in the case suggested a comic side, and it would be

Digitized by Google

easy to turn the whole proceedings into a farce. It does not seem fair, however, that persons whose consciences are so elastic in some directions should string them up so tightly in others as to enable them to enjoy the advantages of citizenship while they evade its duties.

THE DENTAL HOSPITAL OF LONDON.

THE annual dinner of the staff and present and past students will be held on Saturday, Dec. 3rd, at the Hôtel Métropole (Whitehall Rooms), under the presidency of Mr. Storer Bennett. Gentlemen either now or formerly connected with the hospital or medical school who may through inadvertence not have received special notice and who desire to be present are requested to communicate with the dean at the Dental Hospital, 40, Leicester-square.

PAY WARDS IN BRUSSELS HOSPITALS.

ACCORDING to the report of the Conseil des Hospices in Brussels it appears that last year nearly 1100 persons were admitted to the public hospitals as paying patients, the tariff varying from 3 fr. to 15 fr. per diem, for which everything, including professional services and even important operations, was provided. The total amount received last year was 70,000 fr. The medical journals are beginning to complain that this system of admitting paying patients is very unfair to medical men and that reform is needed which must take one of the following shapes: (1) the total abolition of paying wards or (2) the permission for paying patients to select their own professional attendants who must be allowed to have free access to them. It is suggested that the Brussels College of Medical Practitioners should take the matter up.

"MUSCULAR DYSTROPHIES."

IN the *American Journal of the Medical Sciences* for September, 1898, Dr. A. A. Eshner publishes a paper entitled "A Contribution to the Study of the Muscular Dystrophies." The writer first refers to Erb's views—namely, that the changes in the muscles in these conditions are not purely myopathic, but that they may depend upon impalpable nutritional alterations in the ganglion cells of the anterior horns of the spinal cord not capable of demonstration with our present resources—and therefore proposes to designate such cases as come under this group as "muscular dystrophies," thus not indicating definitely any theory of their pathology. Several types of the disease have been described, as, for instance, the idiopathic, the pseudo-hypertrophic, the juvenile or scapulo-humeral of Erb, the infantile of Duchenne, or the facio-scapulo-humeral of Landouzy-Déjérine, and the hereditary of Leyden; but Dr. Eshner thinks it is doubtful if any useful purpose is subserved by this classification, inasmuch as the boundaries of the several so-called types are ill-defined, and many, if not most, cases present features of two or more varieties. It is probable that these several forms represent rather differences in degree and distribution than variations in essential character. Details are then given of 20 cases. Most of the cases are of mixed type, with a predominant tendency to muscular pseudo-hypertrophy. Of the whole number but 4 occurred in females. So far as could be ascertained the first symptoms in the cases reported were noticed in none later than the thirteenth year, in 2 at birth, in 2 during the first year, in 2 during the second year, in 2 during the third year, in 2 during the fourth year, in 3 during the sixth year, in 1 during the seventh year, in 3 during the eighth year, in 2 during the ninth year, and in 1 during the tenth year. The ages of the patients at the times when they came under observation varied from three to twenty-four years. In only 2 of the cases (in brothers) was it definitely ascertainable that similar disease existed in any other member of the same family. In 11 cases one or more of the infectious diseases had preceded the onset of the dystrophic manifestation. In 3 cases there had been falls upon the back before the advent of the symptom of the muscular trouble. Dr. Eshner calls attention to the contraction of the muscles of the upper part of the thigh noted in two of the cases, when the sole of the foot was gently irritated notwithstanding the absence of the plantar reflex.

MEDICO-PSYCHOLOGICAL ASSOCIATION OF GREAT BRITAIN AND IRELAND.

EXAMINATIONS for the certificate of the Association in psychological medicine will be held in London, Edinburgh, Glasgow, Aberdeen, and Dublin, on Thursday, Dec. 15th, 1898. Candidates intending to present themselves for examination should give fourteen days' notice to the Registrar (Dr. Spence, Burntwood Asylum, Lichfield), from whom any further information may be obtained.

THE DIAGNOSTIC VALUE OF KOPLIK'S SPOTS.

IN the *New York Medical Journal* of Oct. 15th, 1898, Dr. J. Sobel confirms the claims of Koplik's spots as a pathognomonic sign both in the pre-eruptive and eruptive stage of measles. As stated in an annotation in THE LANCET of April 30th, 1898, these spots are limited to the mucous membrane of the cheeks and lips and are small, irregular, and bright red. In the centre of each is a minute speck, bluish-white in strong daylight, which, according to Koplik, is absolutely pathognomonic of measles. In the early stages of 35 cases of measles Dr. Sobel never found this sign wanting. On the other hand, he never found them present in 1000 adults suffering from a number of affections or in children affected with various eruptions—varicella, scarlet fever, vaccinia, rötheln, congenital syphilis, urticaria, purpura, erythema multiforme, miliaria, eczema, and bromide and antipyrin rashes. He corroborates Slawyk's observation that the spots occur most frequently opposite the region of the lower molar teeth.

THE SMOKE NUISANCE

ON Nov. 12th a summons was heard at the West London police-court at the instance of the Vestry Clerk of Hammersmith against the East India Produce Company for allowing their chimney at Albert Mills, Upper Mall, to emit black smoke in such quantities as to be a nuisance. The principal witness against the company was Sir William Blake Richmond, who said that the smoke issuing from the chimney was "as black as his coat and so thick that he could not see through it." A vestry sanitary inspector gave similar evidence. The defence was that only yellow and brown smoke issued from the chimney and that smoke-consumers had been applied some two months ago. We do not doubt this fact, but it is quite evident that the smoke-consumers do not do their work properly. Mr. Rose, in describing Sir William Richmond as a public benefactor, referred to the difference of opinion as to the colour of the smoke, and said that that gentleman from his profession was the most fitting witness to describe it. He should make a prohibitory order for the prevention of the recurrence of the nuisance and should allow the vestry five guineas costs. We are glad to see that the incriminated company did not put forward any plea about not being able to get Welsh coal, for whether they can or not that has nothing to do with it. We should like to see the sanitary authorities take in hand the case of certain big restaurants and hotels which are much to blame as regards polluting the air, and also we should like to know whether there is any power by which the London County Council can make it obligatory on the builders and architects of any new house or houses to fit the fireplaces

Digitized by Google

with some kind of smoke-preventing apparatus. If the council has not such powers the sooner it applies for them the better. New houses are being built every day, and it is ridiculous to allow new centres of pollution to arise without hindrance.

THE RECORDER AND THE SUPERINTENDENT.

OUR special correspondent at Belfast called attention last week to the extraordinary action of the Belfast Recorder in declining to allow Dr. Graham, the medical superintendent of the asylum, a fee for making an affidavit in reference to the condition of a lunatic and for attending the court. Dr. Graham's action has now received considerable official support, as will be seen in our special correspondent's letter in another column, and he is to be warmly congratulated upon the dignified way in which he has pressed his rights. It is to be hoped that the Recorder, who is on all accounts a most kind as well as honourable gentleman, will, now that both his statements in reference to Dr. Graham's predecessor have been disproved and his legal decision called in question, see that the proper course is to reverse his previous judgment. In our opinion life would be intolerable to medical men if they were to be compelled to attend civil courts and prepare important medical reports simply because they are Government officials.

ANKYLOSTOMUM DUODENALE.

IN the *Berliner Klinische Wochenschrift*, No. 36, 1896, Dr. W. Ginn and Dr. Martin Jacoby published certain observations which they had made on the presence of the ankylostomum duodenale and other parasites in the intestines of natives of India and they arrived at two main conclusions: (1) when the ankylostomum has gained a hold amongst a native tribe of India it spreads with great rapidity amongst the members of the tribe; and (2) it appears very probable that a person may have the ankylostoma in his intestine without being the subject of ankylostomiasis. In the summer of this year, 1898, the same observers had opportunities of examining the stools of several natives. Of the fæces of 8 natives of Ceylon, in 8 the ova of ankylostomum duodenale were found, in 7 those of the trichocephalus dispar, and in 6 those of the ascaris. In the stools of 6 natives of Madras in 6 were observed the ova of ankylostomum duodenale, in 6 those of trichocephalus dispar, and in 5 those of ascaris, and in 2 of the Madras natives the larvæ of anguillula intestinalis appeared. The first of the above proportions was therefore corroborated by the new investigations. As supporting the second of their conclusions Dr. Ginn and Dr. Jacoby found that a large number of Asiatics and Africans in whose stools the ova of the ankylostomum were found exhibited no signs of anæmia. Amongst certain tribes there seemed to exist a certain immunity from ankylostomiasis. But the immunity was limited and by no means absolute.

THE CHEMICAL SOCIETY.

WHEN the idea was mooted more than half a century ago of forming a chemical society doubts were expressed by several chemists as to whether success would attend the experiment. The Chemical Society is now amongst the most active scientific bodies connected with the parent Royal Society. We believe, too, that financially its position is very satisfactory. The work done by the Fellows of the Chemical Society during the past fifty years embraces some of the most important discoveries which have appeared in the annals of the world of scientific research. Amongst the fellows are six past presidents who have belonged to the society for half a century. These are Sir Joseph Henry Gilbert, Sir Edward Frankland, Professor William Odling, Sir Frederick Augustus Abel, Dr. Alexander William Williamson, and Dr. John Hall Gladstone. The death of Lord Playfair a few months ago removed a member who had also served as a president. A banquet in honour of these scientific men was projected early in the year and was eventually arranged to take place on June 9th. In consequence, however, of the death of Lord Playfair the banquet was postponed till Nov. 11th, when a very representative company of distinguished men of all branches of science entertained the surviving past presidents who have been Fellows for half a century and whose names appear above. In replying to the toast of "The Past Presidents" which was given by the present President, Professor Dewar, each veteran gave a most interesting historical sketch of the progress of chemistry during the last five decades. The guests present included Mr. Haldane, Q.C., M.P., and Dr. Böttinger of the Reichstag, who replied to the toast proposed in their honour by Dr. T. E. Thorpe, the treasurer of the society. Congratulations were received and announced from the Russian and German chemical societies. Professor Michael Foster, who followed Lord Lister in an interesting speech, remarked that when the British Association met their French friends at Dover and Boulogne next year Fashoda would have been forgotten and they would not be using the resources of science to make the two nations as small as possible but each would be using the resources of the other to advance their common knowledge.

THE SPECTACLE MAKERS' COMPANY'S OPTICAL EXAMINATION AND THE EXAMINATION OF THE BRITISH OPTICAL ASSOCIATION.

OUR contemporary the *Optician* gives in this week's issue the questions set by the examiners of the above bodies for their optical examinations. The examination of the Spectacle Makers' Company is the first of them and is divided into two parts—a *vivâ voce* and a written, the latter occupying two hours and a quarter. It is stated that 93 candidates presented themselves and that amongst these there were a large number of old members of the industry, the provinces being well represented by candidates from Leeds, Tunbridge Wells, Deal, Tenby, Carlisle, Kilmarnock, and other places. The questions seem to have been carefully thought out, and if anything like satisfactory replies were obtained the standard of knowledge in the possession of the opticians is very high, and it is clear that those who pass the examination will not only be thoroughly grounded in their subject, but will be very competent judges of the prescriptions sent to them by ophthalmic surgeons. As it is certain that a large proportion of the public do, and will always continue to, apply to the optician for incipient failure of vision it is obvious that the glasses selected by the optician should be given with judgment and a sound knowledge of the principles of optics. At the same time the opticians should remember the motto, "Ne sutor ultra crepidam," and take care when unusual or suspicious phenomena are observed to recommend the patient to obtain the advice of the surgeon. We append a few of the questions set at the former of these examinations. 1. How would you determine the focal length of a simple biconvex lens with faces of equal curvature? Give all the practical methods you know of. 2. In what way is the position of the principal focus of a lens dependent upon the choice of the curvatures? Illustrate your answer by reference to the positions of the front and back foci of a plano-convex lens of + 20 D. Does it matter which surface you turn towards the source of light as regards definition? 3. A prescription is given you as follows: − 3 D. C. axis horizontal ◯ + 1·5 D. C. axis vertical R. & L. State the different methods of working such a lens and give reasons for your choice of curves. 4. A boy, aged ten years, has vision = $\frac{1}{18}$ and with − 2·5 D. S. he sees $\frac{2}{18}$, but on testing, his P.P. is found to be at 12 cm. What is probably his defect and

Digitized by Google

give your reason? The British Optical Association's examination has also been held this month and twelve candidates presented themselves, out of whom only one failed to pass. This examination occupies about two and a half hours and is divided into three parts—optic, dioptric, and ophthalmometric. Amongst the questions were the following: 1. Show how images formed by concave lenses are always vertical, erect, and diminished. 2. Transpose the following lenses into other combinations: (*a*) 1·73 cyl. axis 45° ⊂ + 3·25 cyl. axis 135°; (*b*) + 3·00 spher. ⊂ − 1·5 cyl. axis 105°; (*c*) + 1·25 sph. ⊂ + 2·75 cyl. axis 90°. 3. In dislocation of the crystalline lens, the periphery of the lens being located, say, in the middle of the pupil; how would you prescribe lenses to assist the refraction for distance? These are sufficiently reasonable questions and no exception can be taken to them from a professional point of view. We must add, however, that in the ophthalmometric part of the examination of this association some of the questions trench on purely medical subjects and imply that the young optician has gone somewhat beyond his *métier*—for example, Question 3 is, How would you diagnose tobacco amaurosis? Question 4 is, How would you measure scotoma? Question 7 is, What are the indications that would lead you to suspect incipient glaucoma? If the candidate be expected to diagnose tobacco amaurosis, why should he not know the retinal changes in Bright's disease and diagnose the nature and position of an intracranial lesion from the observed defects in the field of vision? Surely, all this is quite outside the optician's work.

SWEET SPIRIT OF NITRE.

NOW that the expression "sweet spirit of nitre" is included in the new Pharmacopœia as a synonym for spirit of nitrous ether druggists are bound to supply this article when asked for under the popular name and the article may be demanded in accordance with the strength officially laid down. It is well known that when druggists in the past were asked for sweet spirit of nitre they now and then supplied an article of deficient strength against which no remedy could be provided because sweet spirit of nitre had no official existence and no recognised definite strength. However, the new Pharmacopœia now provides that when sweet spirit of nitre is asked for the official spiritus etheris nitrosi shall be supplied. It is early yet to decide upon the effect of this alteration but in one case an inquiry has been made. Dr. Bernard Dyer in his report as the analyst to the county of Leicester found that of the 51 samples of sweet spirit of nitre obtained 23 were of first-class quality, 21 were fairly good, while 7 samples were decidedly unsatisfactory. In the last instances the retailing druggists were only warned, as it was considered probable that these specimens had been in stock before the new Pharmacopœia was published. The inquiry is instructive and timely and it should place retailing druggists on their guard so that they may not unwittingly commit an offence under the Food and Drugs Act.

MEDICAL OFFICERS OF HEALTH AND PRIVATE PRACTICE.

THE vacancy of the post of medical officer of health of the Burgh of Perth is the cause of much discussion as to whether the newly-appointed medical officer should be debarred from private practice and at the same time of course be offered suitable remuneration. Hitherto in the Burgh this has not been the case, although the county medical officer is debarred. The late medical officer for the Burgh, Dr. Simpson, now dead, had, we believe, £105 per annum as medical officer and £52 10*s*. as police surgeon, and was in addition allowed to carry on private practice. To our minds it is in no way desirable that the medical officer of health should be also in private practice, for the holding of the two posts must at times bring him into disagreeable and anomalous positions. To begin with he might very well often come into conflict with his fellow practitioners and as he is in private practice himself, with professional rivals. Also cases might arise where as medical officer of health his duty might be directly opposed to his interests as a practitioner. It is for these reasons that we hope that the Burgh of Perth will see its way to appoint a medical officer of health who will be debarred from private practice but who will also receive sufficient remuneration to enable him to devote his whole time to the duties of his office and who will be in a position to exercise them without fear or favour.

THE KITCHENS OF PARISIAN EATING-HOUSES.

IN December, 1897, the Société Française d'Hygiène resolved to appoint a commission to inquire into the sanitary conditions under which the kitchen employés in Parisian hotels, restaurants, and other establishments of a similar character where food is prepared for public consumption, are compelled to carry on their work, and in due course a report embracing the whole subject was published in the *Journal d'Hygiène* over the signature of Dr. Bruhat, the secretary of the commission. It is not too much to say that the condition of things disclosed in this exhaustive report can only be described as deplorable. Until a few years ago all kitchens, with their offices and annexes, where eatables were cooked for the use of the public were under Government surveillance by virtue of several decrees dating back upwards of twenty years, but in July, 1894, this important safeguard to the general health was withdrawn. A Ministerial circular suddenly appeared directing the sanitary inspectors of the municipality of Paris to abstain in future from the inspection of eating-houses of every description because it had been ruled that such establishments were no longer to be regarded as trading places but rather as partaking of the nature of private houses. And yet, to judge by the copious extracts which Dr. Bruhat has cited from official reports dated prior to the retrogressive circular, the need for efficient supervision and control remained as urgent as ever. Writing to the Minister of Commerce in 1892 M. de Maroussen, with reference to the junior employés in public kitchens, says: "A wretched existence; cooking arrangements badly installed; hygienic conditions deplorable." In July, 1888, MM. Hudelo and Napias wrote the following description of the kitchen in one of the principal boulevard restaurants:—

"Everything is on the narrowest scale and one was consequently roasted on all sides. The ceiling is scarcely 3 metres high, while overhead the gas flares. Under foot are the pipes from the range, between which and the grill the distance is so small that if two men want to pass each other one of them has to squeeze himself up against the heated metal. To the left is the spit; alone the right end is unoccupied. Imagine eight or ten people working together under such circumstances! This is, nevertheless, the state of affairs in 80 per cent. of the kitchens not only in Paris but also in our larger towns, and even in Algeria."

In a report by M. Schaere the following passage occurs:—

"The kitchen is underground, less than 2½ metres high, and along with the larder and offices receives its light and air through narrow slits, three opening at the level of the street and two on the garden. There are two ventilators, but they work badly. The street sewer being on a higher level than the floor it is impossible to drain into it, so a cess-pit has been sunk which has to be emptied by pumping. The smell from it is most offensive. The sink drains into the sewer, but sometimes the contents of the latter inundate the kitchen. A urinal hard by is in communication with the cess-pit."

Another reporter writes:—

"The kitchen is invariably the filthiest spot in the house. ..... In some establishments you will find a latrine in direct communication with the kitchen or else with the

Digitized by Google

larder, but this is a trifle, seeing that in others the hands are obliged to convert provision-tins into urinals, being forbidden to obstruct the narrow space by passing to and fro."

Working from five or six o'clock in the morning until ten o'clock at night, with only short intervals for eating, but none for repose, it is no wonder that the hapless people whose fate has made them Parisian cooks should suffer excessively from preventable diseases, chiefly tuberculosis and gastro-hepatitis, and be the victims of an abnormal mortality. Their surroundings are insanitary to a degree almost beyond belief, and in addition they have to breathe an atmosphere heated "not merely up to 104° F., which is the ordinary temperature in Parisian kitchens, but even as high as from 140° to 160°." The number of cooks employed in the public eating establishments of Paris is estimated at 20,000, of whom 8000 are males and 12,000 females. During the quinquennium 1891–95 the death-rate among them was 26·98 per 1000 per annum, or about double that of the adult population of the city. The same factors which are responsible for the unhealthiness thus so lamentably exemplified must also react disadvantageously on the food prepared. For the sake of the poor people chiefly concerned and also in the interests of the immense number of visitors to Paris, of whom British subjects form no small part, who naturally are obliged for the most part to frequent hotels and restaurants, it is imperatively necessary that remedial measures of a radical description should be forthwith devised for the crying evil which has been so fearlessly exposed by the Société d'Hygiène. The commission, in conclusion, strongly recommend the immediate resumption of systematic supervision in all kitchens where food or comestibles of any kind are prepared for general use; and they are also of opinion that every employé should be allowed at least one free day per month. These recommendations do not err on the side of unreasonableness, but no doubt it is better to ask for a little and get it than to paralyse a timid executive by an excessive demand.

CHRISTOPHER COLUMBUS AND THE MEDICAL PROFESSION.

IT is stated in *Italia Termale* that Dr. A. M. Fernandez de Ybarra has published an interesting work on the medical history of the expeditions which Christopher Columbus undertook in his search for a new world. During the great discoverer's first voyage his slender following, which all told numbered but 120 souls, included two physicians—to wit, Master Alonzo, on board the caravel *Santa Maria*, and Master Juan, on board the *Pinta*. When Columbus returned to Spain the last-named officer remained behind at Fort Navidad, and made one of the thirty-eight victims who were massacred by the natives of San Domingo. The principal medical officer of the second expedition, which consisted of 1500 men, and sailed from Cadiz in the month of September, 1493, was Dr. Diego Alvarez Chanca, of Seville, physician in ordinary to the King and Queen of Spain. In a report addressed to Ferdinand Columbus referred to this officer in the following flattering terms: "I make a point of directing the attention of your Highness to the never-ending work wherewith Dr. Chanca is overwhelmed in consequence of the heavy sick roll together with the dearth of provisions; but in spite of all difficulties he evinces the utmost zeal in everything that concerns his art. Your Highness having left me free to fix the amount of his remuneration (although it is perfectly certain that neither I nor anyone else in my position could give him a sum even approaching what he would gain on land), I have opened for him an annual credit of 50,000 maravedis."[1] Dr. Chanca is given the credit of having cured Columbus of a malignant fever which had brought him to death's door, and he is also said to have been the first person to write a description of the New World, his contribution taking the form of a report to the Municipal Council of Seville. On his return to Spain he produced his "Commentum Novum in Parabolis Divi Arnoldi de Villanova" which was published at Seville in 1514. But it was not solely to the members of the medical profession who sailed in his company that Columbus expressed his indebtedness. Paolo dal Pozzo Toscanelli, a famous physician and astrologer of Florence, gave him what is described as excellent advice regarding the possibility of reaching India from the West, and in order to simplify matters likewise presented him with a map showing the course he ought to steer. The value of the Florentine's counsel is open to question, but there was another less pretentious practitioner who undoubtedly was able to render the hero an inestimable service at a turning point in his career. Discouraged by persistent opposition and well-nigh broken-spirited, Columbus had sought asylum in the convent of Santa Maria della Robida in Andalusia, whereupon the Prior believing him to be mad sent for Dr. Garcia Fernandez, an unassuming country surgeon from the neighbouring hamlet of Palos do Moguer. Happily the village Galen was a man of discernment. He quickly perceived that his patient was no lunatic but a man of genius, and instead of consigning him to chains and a dungeon after the fashion of the day he not only restored him to health by his treatment but also won for him the goodwill of the Prior, who furnished him with means and introduced him at Court. It is generally stated that Columbus died from gout, but Dr. de Ybarra disagrees with the authorities who are responsible for this diagnosis. In his opinion death was due to cardiac complications consequent on chronic rheumatism, and in support of this contention he adduces the testimony of several persons who aver that they saw the dying navigator during the last month of his life and that his body was enormously swollen from the chest downwards.

[1] About £144 sterling.

YELLOW FEVER IN NEW YORK CITY.

THE first case of yellow fever which has occurred in New York city for many years terminated fatally about three weeks ago. Colonel Waring, one of the best known public men in New York, who made a name for himself and earned the lasting gratitude of his fellow citizens under the *régime* of the late mayor by efficiently and thoroughly cleansing the streets, had been sent by the United States Government to Cuba to make a report on the condition, and to suggest plans for the sanitary regeneration, of Havana and Santiago. Colonel Waring having completed his task arrived at New York on Tuesday, Oct 25th. On his arrival he complained of feeling unwell, but thinking that he was suffering from a slight attack of malaria he proceeded to his home to rest for a day or two before going to Washington to report the results of his mission to President McKinley. The family physician was called in and he decided that his patient was suffering from a severe cold and it was not until the Thursday that suspicions were aroused as to the true nature of the malady. Dr. Doty, the health officer of New York Harbour, was summoned in consultation and he quickly came to the conclusion that Colonel Waring had contracted yellow fever. At 1 A.M. on Saturday, Oct. 29th, the dreaded black vomit made its appearance and, becoming weaker and weaker after each recurrence of the vomit, Colonel Waring expired at eight o'clock on Sunday morning. Immediately after death the body was placed in a lead coffin which was hermetically sealed and was conveyed on board the Health Department boat to the State crematorium on Swinburne Island, where it was burned. Much fear was evinced that the contagion might spread and every sanitary

Digitized by Google

precaution was taken to prevent such an occurrence. It was pointed out, however, by experts that at this time of the year and in a city like New York where the hygienic arrangements were so good there was no cause for alarm. Colonel Waring was an authority on sanitary engineering and he had written many books on the subject. It will be remembered that in 1896 Colonel Waring made a tour of the large towns of the European continent and of Great Britain in order to inspect their different methods of sewerage, draining, and street cleaning, the results of his investigations being set forth in a series of valuable articles.

DR. GIUSEPPE SANARELLI, of the Uruguayan Medical School and Director of the Hygienic Institute at Montevideo, whose discovery of the microbe of yellow fever has brought him much distinction, has been offered by Dr. Baccelli (Minister of Public Instruction) the chair of Hygiene in the University of Bologna left vacant by Professor Roncati. The offer was made in accordance with the express wish of the Bolognese medical faculty.

THE Alvarenga prize of the College of Physicians of Philadelphia for 1898 has been awarded to Dr. S. A. Knopf of New York City for his essay, entitled "Modern Prophylaxis of Pulmonary Tuberculosis and its Treatment in Special Institutions and at Home."

THE County Council of Wiltshire on Tuesday last, after a debate lasting nearly three hours, resolved by 31 votes against 29 to appoint a medical officer of health to the county at a salary of £500 per annum with travelling expenses.

A DONATION of £1000 from "H." and one of £500 from "E." have been received towards the Charing-cross Hospital special appeal for £100,000.

THE ROYAL COMMISSION ON THE METROPOLITAN WATER-SUPPLY.

THE thirty-third sitting of the Royal Commissioners was held at the Guildhall, Westminster, on Nov. 8th. Lord Llandaff, the chairman, presided, and the other Commissioners present were the Right Hon. John William Mellor, Q.C., Sir John Dorington, M.P., Sir George Barclay Bruce, Mr. de Bock Porter, Major-General Scott, and Mr. Robert Lewis.

At the commencement of the sitting Mr. John Hollams continued his evidence. The other witnesses examined were Sir Henry Knight, chairman to the Southwark and Vauxhall Company; Mr. Walter Hunter, engineer to the Grand Junction Company; Mr. Restler, engineer to the Southwark and Vauxhall Company; and Mr. Thomas Parkes, engineer to the Lambeth Company.

Mr. JOHN HOLLAMS, in answer to the CHAIRMAN, said that the proportion of interest on the Debenture Stock which it would be necessary to issue for carrying out the proposed inter-communication between the companies could be arranged by an arbitrator. In case of water being taken from the Southwark and Vauxhall Station at Battersea each company should, in his opinion, pay the interest on the debentures issued in the manner arranged by the arbitrator. If one or more companies used the water that company or those companies should pay for the amount used.

In answer to Mr. DE BOCK PORTER the witness said that if the mains of one company were used to conduct water for the use of another a payment for the "way leave" should be charged.

In answer to the CHAIRMAN the witness said that in the East-end of London many houses were supplied at a loss to the company; practically the rich were made to pay for the poor. The Staines Reservoir Act prohibited intersale of water derived from that source and there were many clauses in existing Acts of the water companies which would have to be repealed to render an inter-communication system legally possible. Statutory provisions would also have to be made to give the water companies power to spend money outside their authorised districts of supply. The witness thought, however, that a scheme of inter-communication might be sanctioned by a very simple Act of Parliament.

Lord LLANDAFF said that the Commissioners wished to hear from the engineers of the water companies what their resources were; to know what extra amount of water each company had over that required for the supply of their customers; and whether they possessed sufficient plant for the filtration and pumping of that water.

A question arose with regard to the legality of a circular recently issued by the Local Government Board referring to the Act of 1897, and on this point the CHAIRMAN said he would not take upon himself to express the slightest opinion. The witness contended that the companies were not bound to supply water in times of drought and that should the companies carry out a scheme for inter-communication they would lay upon themselves a serious burden for the benefit of the public.

Sir HENRY KNIGHT, chairman to the Southwark and Vauxhall Company, said that in his opinion the scheme of inter-communication which had been brought before the Commissioners was practicable. It was necessary that some such scheme should be adopted to satisfy "public outcry." The witness said it would be possible for a comparatively small sum to make some provision for inter-communication. The Battersea scheme must be looked upon as a "continuous perpetual" arrangement made to satisfy "public anxiety." The witness did not admit that there had been an insufficient supply of water in East London during the present summer. There was, he said, "not such an admirable supply" as usual and he admitted not a constant supply. If any want of water had been experienced it was due to "the ridiculous system" which had recently been inaugurated of building houses without a sufficient storage for water. The witness emphasised his opinion by thumping the table and suggested that no sane man would have a house without sufficient storage of water.

The CHAIRMAN pointed out that the Commissioners had seen specimens of matter found in cisterns in the East-end and that they were not attractive. The witness related his personal experience that when his cistern was cleared out "not half a teacupful of sediment" was found in it, and he advocated a cistern with a sloping bottom, an arrangement, it may be remembered, which has already been brought before the Commissioners, and which has, as the Chairman pointed out at the time, the merit of conducting any deposit straight into the supply-pipe of the consumers for their immediate consumption.

In answer to Major-General SCOTT the witness said he could not tax his memory with regard to the exact area of the filter-beds of the company of which he was chairman, but he was not prepared to deny that they had only twenty-two acres of filter-beds for the filtration of 46,000,000 gallons of water daily. He stated that the East London Waterworks Company had been supplied with water derived by this company from sources other than the Thames. The supply given was what he called "manufactured water" (filtered water). With regard to the amount of water drawn by the metropolitan companies from the Thames the witness gave it as his opinion that no limitations should be placed with regard to the amount which they should be allowed to take. As long as London wanted water to drink it should be taken from the Thames. It was perfectly useless and unnecessary that anything like 200,000,000 gallons should be allowed to flow over Teddington Weir. It occasionally happened, doubtless, that barges got aground, but there were two tides a day so that they were able to get off.

Mr. WALTER HUNTER, engineer to the Grand Junction Waterworks Company, in answer to the CHAIRMAN, said that in his opinion the Battersea scheme would be useful. The scheme could be carried out by next summer. The cost of the new mains and connexions would, roughly speaking, come to about £255,000. Ultimately a new 36 in. main would have to be made from the Thames intake to the Battersea station. The other expenses of the scheme would be a payment for the use of reservoirs at Campden-hill and a rent charge to the Southwark and Vauxhall Company for their Battersea station.

Mr. RESTLER, engineer to the Southwark and Vauxhall

Digitized by Google

Waterworks Company, agreed with the last witness that if the Battersea scheme were carried out it would be the best solution that could be arrived at for the whole question.

In answer to a question from the CHAIRMAN the witness pointed out that there would be great difficulties in supplying the East London Waterworks Company with an extra amount of water by the passage of water through the mains of more than one water company. The chief difficulty arose from the fact that the pressures in the mains of different companies varied from one another and that the pressures varied in the mains of each company at different times during the day. From this simple consideration it followed that a passage, for example, of the Chelsea Company's water through the mains of the Southwark and Vauxhall Company to those of the East London Company would practically not be a good working scheme.

Mr. THOMAS F. PARKES, engineer to the Lambeth Company, said that his company with their present plant and equipments would be unable to spare any water during the time of maximum supply—that is to say, in the months of July and August. They had, however, storage works in progress which would enable them to supply 5,000,000 or 6,000,000 gallons daily. They had not, however, legal power to abstract that extra amount of water from the Thames. The witness stated that they obtained a considerable amount of water from gravel beds near the Thames.

The thirty-fourth sitting of the Royal Commissioners was held at the Guildhall, Westminster, on Monday, Nov. 14th. The Commissioners present were Lord Llandaff (the chairman), Major-General Scott, Mr. de Bock Porter, and Mr. Robert Lewis. The whole of the sitting was occupied by the examination of Mr. William Booth Bryan, engineer to the East London Waterworks Company.

It may be well to mention here that since the last sitting a paper has been printed for the benefit of the Royal Commissioners giving a plan showing the proposed trunk mains which would have to be made in the Battersea scheme for supplying water to the various companies. The paper is called "Amended Report of the Engineers of the London Water Companies prepared in view of events which have happened since their report, dated October, 1897, on the proposal to make interchangeable connexions between the mains of the several companies." It will be remembered that the stations which would be used are the Battersea station of the Southwark and Vauxhall Company, the Campden-hill station of the Grand Junction Company, Claremont-square station of the New River Company, the Nunhead station of the Southwark and Vauxhall Company, and the Brixton Hill station of the Lambeth Company. Some of the mains which at present exist would be utilised. These are, the main which conducts the unfiltered water to the Battersea station, the main which conducts the filtered water from Battersea to Nunhead, and the 24 in. main which conducts water to Claremont-square. The new mains which would have to be laid are: (1) from Battersea to Campden Hill; (2) from Campden Hill to Poland-street, where it would join an existing main belonging to the New River Company; (3) from Battersea to the Angel, Islington, to a New River main; (4) from Battersea to Brixton Hill; and (5) from Nunhead to the Tower subway through which the water would pass for the supply of the East London Company's mains. At this sitting no intimation was made that the Battersea scheme was unanimously accepted by the directors of the various metropolitan water companies.

Mr. BRYAN, in answer to the CHAIRMAN, said that he had been sixteen years chief engineer to the East London Waterworks Company. The population at present supplied by the company was 1,300,000. The quantity supplied monthly from June to October during the year 1898 was as follows:—June, 42,563,000 gallons per day; July, 44,959,000 gallons per day; August, 43,170,000 gallons per day up to August 22nd, when they commenced the intermittent supply in place of the constant; August, 40,656,000 gallons per day as the average of the whole month; September, 33,149,000 gallons per day as the average of the whole month; and October, 34,202,000 gallons per day as the average of the whole month.

The CHAIRMAN said that he had received a communication from a gentleman named Glover, living at Upton Park, who said that in his case it would be more nearly the truth to say that the house received 25 gallons than that that amount was supplied to each consumer. He further observed that his was not an isolated case. On many days water did not reach his cisterns, so that he was placed in a worse position than that of the people who obtained their water direct from the main.

The witness admitted that a difficulty had arisen in the case of some of the high cisterns when the water was first turned on, because the lower cisterns had first to be filled, and only after this was done could the water reach the higher cisterns.

Mr. DE BOCK PORTER asked if in that case in some houses the highest cisterns got no supply at all. The witness, in reply, said that if that were the case the customers would have to get their water from taps on the lower floors. He added that he had received very few complaints and that if the gentleman (Mr. Glover) had written to him he would have been able to see whether the fittings of the house were in an efficient state. In many cases it was found that the ball-taps were out of order. It occasionally happened also that the taps were left running in a street so that the water did not reach some of the cisterns. In one case the amount of water which was allowed to run away through open taps was so great that the sewer man came to the company's foreman and stated that he could not go into the sewer because of the immense amount of water which was running away. When the turncock turned off the taps the water in the sewer was immediately lowered and the man was able to resume his work. During the time in which the company gave an intermittent supply they published a time-table like a railway time-table saying at what hour the water would be turned on.

The CHAIRMAN asked if when water was turned on in the morning from six to eight o'clock it would be necessary for a would-be consumer to rise and turn on his tap? and he suggested that as an alternative a water-rent payer might think it advisable to leave the tap running rather than rise at so early an hour. The witness admitted that this might be so and said that the company had less trouble at the present time than they had had at first with regard to the number of taps which were left running. The supply of water was still restricted to four hours a day throughout the whole district. The witness handed in a paper giving the daily supply of water during the months of July, August, September, and October. It is as follows:—

Source from which water is taken.	Gallons pumped into the district daily on the average during:—			
	July.	August.	September.	October.
1. River Lee	9,479,000	6,354,000	1,032,000	4,693,000
2. River Thames and wells	16,967,000	19,056,000	19,153,000	18,419,000
3. Storage reservoirs.	17,500,000	9,900,000	4,600,000	*Nil*
4. New River Company.	1,013,000	5,346,000	6,129,000	6,093,000
5. Southwark and Vauxhall Company.	—	—	2,029,000	4,801,000
6. Kent Company.	—	—	206,000	196,000
Total pumped into district of supply	44,959,000	40,656,000	33,149,000	34,202,000

The storage reservoirs, which have a capacity of 1,200,000,000 gallons, were filled on June 20th. The amount of water taken during the months of July, August, and September reduced them to a very low state at the end of that month. The witness contended that there was really no water famine because during the driest time 33,000,000 gallons a day were distributed and this quantity amounted to an average of 25 gallons per head. He contended that had there been proper cisterns or means of storage little inconvenience would have been felt. Cisterns had been removed from the houses contrary to the wishes of the company soon after a constant supply of water was first given. The sanitary officers and authorities could not insure cleanliness of the cisterns and for that reason they had caused them to be removed. The supply of covered cisterns would remedy this evil, but the company had not sufficient power to enforce such a regulation. The company had provided 30,000 jars for storage of water and had put up stand-pipes to the mains so that water could be drawn from them. In the opinion of the witness the real evil was due to the absence of cisterns. This deficiency caused considerable inconvenience even in case of a temporary breakdown in the water-supply, which might be due to the fracture of a main.

In reply to the CHAIRMAN the witness said that it was

Digitized by Google

difficult to say whether the company had power to order that cisterns should be put into the houses of existing customers. There was a clause in one of the Acts of the company which provided that cisterns should be fixed. The clause, however, did not specify the size or character of the cistern and consequently the company had practically little control. In some cases cisterns of about the size of a hat had been put in. In many cases, especially in the Essex district, it had been the habit of the builder to fix a cistern and demand that the water should be laid on to a new house. After the water had been laid on the cistern was removed and taken to the next house. By this simple device one cistern had been made to do duty for a whole row of houses.

The CHAIRMAN asked whether it was not possible to prevent so transparent a fraud and the witness replied that there would be many difficulties in obtaining a conviction in such a case.

The CHAIRMAN asked how the company proposed to obtain a constant supply during the year 1899. The witness replied that should a similar drought occur he thought that with the connexions already made the company would be able to keep up a constant supply by obtaining the amount of water given in a table which he handed in. The witness assumed that 46,000,000 gallons in July, 45,000,000 gallons in August, 44,000,000 gallons in September, and 42,000,000 gallons daily in October would be required to keep up a constant supply. The table is as follows:—

Source from which water is taken.	Gallons pumped into the district daily on the average.			
	July.	August.	September.	October.
1. River Lee	10,000,000	6,000,000	1,000,000	4,000,000
2. River Thames and wells	24,000,000	24,000,000	24,000,000	24,000,000
3. Storage reservoirs	*Nil.*	3,000,000	7,000,000	2,000,000
4. New River Company and during August, September, and October with the assistance of the Grand Junction and West Middlesex Companies.	6,000,000	6,000,000	6,000,000	6,000,000
5. Southwark and Vauxhall Company	6,000,000	6,000,000	6,000,000	6,000,000
Total pumped into district	46,000,000	45,000,000	44,000,000	42,000,000

The witness said that in order to carry out the arrangements which he had indicated they would take no water from their storage reservoirs until the end of July and that the position would, he hoped, then be as follows:—

Storage water	1,200,000,000 gallons.	
August, 3,000,000 gallons per day ...	93,000,000 ,,	
	1,107,000,000 ,,	(i.e., at end of August.)
September, 7,000,000 ,, per day ...	210,000,000 ,,	
	897,000,000 ,,	(i.e., at end of September.)
October, 2,000,000 ,, per day ...	62,000,000	
	835,000,000 ,,	(i.e., at end of October.)

The company propose for the present to "husband" their storage water and hope to fill their reservoirs and then to keep them full until August 1st. They would then be able to give a constant supply and would have 835,000,000 gallons in store at the end of October. It might also be possible for them to obtain an additional 2,000,000 gallons a day from the New River Company, which would get this amount supplied by the Grand Junction and West Middlesex Companies. The means of inter-communication which existed at present between the systems of the East London Waterworks and those of the other companies were: 1. By means of the River Lee. (This, however, is not strictly inter-communication. The arrangement has already been fully described in THE LANCET. The so-called inter-communication amounts simply to this—that the New River Company refrains from taking a certain amount of water which, therefore, is allowed to flow down the Lee to the intake of the East London Waterworks Company. The matter was made clear to the Commissioners by questions asked by Major-General Scott.) A new 24 in. main had been laid from the Grand Junction Company's district to the New River Head and a connexion to this main had been made by the West Middlesex Company. It was suggested that (1) some quantity of water might be supplied by these two companies to the New River and that a corresponding amount of water should be passed by the New River Company to the East London intake at the River Lee. 2. The Kent Company could supply water through two 4 in. mains which passed under the Thames in the Blackwall tunnel. 3. There was also a connexion with the mains of the Southwark and Vauxhall Company. A 20 in. main from Nunhead reservoir had been continued through the Tower subway (this subway belongs to the London Hydraulic Company and an easement has been granted to the East London Waterworks Company for a term of years). This main can convey 5,000,000 gallons of water daily, but is capable of carrying more. The East London Waterworks Company propose also by agreement with the Grand Junction Company to make additional connexion between their Thames main and the Campden-hill reservoir of the latter company. By this means it is hoped that they may obtain another 2,000,000 gallons daily.

The thirty-fifth sitting of the Royal Commissioners was held at the Guildhall, Westminster, on Tuesday, Nov. 15th. The Commissioners present were Lord Llandaff (the chairman), Sir John Dorington, M.P., Sir George Barclay Bruce, Mr. de Bock Porter, and Mr. Robert Lewis. The witnesses examined were Mr. BRYAN, engineer to the East London Waterworks Company, who was cross-examined by Mr. Pember on behalf of the water companies, by Mr. Balfour-Browne on behalf of the London County Council and by Lord Robert Cecil on behalf of the Hertfordshire County Council. The witness exhibited and explained a map showing the geological formation of the valley of the Lee. The other witnesses examined were Mr. Hervey, engineer to the West Middlesex Water Company; Mr. Hack, engineer to the Chelsea Company; Mr. Morris, engineer to the Kent Company; and Mr. Francis, one of the engineers to the New River Company. These gentlemen all gave evidence in favour of the Battersea scheme, which was more fully explained by Mr. Collins, an engineer to the New River Company.

Mr. PEMBER, on behalf of the metropolitan water companies, said that the Battersea scheme had the unanimous sanction of the companies.

Sir ALEXANDER BINNIE gave evidence to the effect that the scheme was unnecessary.

Mr. BALFOUR-BROWNE, on behalf of the London County Council, said it was more a matter for "argument" than for "evidence" and he wished to address the Commissioners. He suggested that the East London Waterworks Company's undertakings might now be bought cheaply because it was a defaulting company.

The Commissioners unanimously decided not to hear counsel on either side and at the conclusion of the sitting it was intimated that the Commissioners would meet privately on Monday next to consider the evidence which had been taken with regard to the inter-communication of the companies' mains.

The next public sitting of the Commissioners will be held on Tuesday, Nov. 22nd.

THE BATTLE OF THE CLUBS.

ANCIENT ABBEY LODGE, WALTHAM ABBEY, AND THEIR MEDICAL OFFICER.

ON Oct. 27th a meeting of the members of the Ancient Abbey Lodge of the Independent Order of Oddfellows, Waltham Abbey, was called for the purpose of presenting Dr. J. B. Henderson, who has for twenty-five years filled the office of lodge surgeon, with a testimonial to the worth in which they held his services. Hitherto the articles which we have inserted under the heading, "The Battle of the Clubs," have been unfortunately all of one tenour. It is, therefore, with all the more pleasure that we insert an account of the proceedings, which did the utmost credit to all concerned, and we must specially congratulate the chairman upon the

Digitized by Google

facts—for they are facts and not merely opinions—mentioned in his speech.

The chair was taken by the Rev. J. H. Stamp and there was a large attendance of members and friends. After the usual loyal and patriotic toasts the chairman said: We come now to the most important part of our programme. We are assembled in our lodge-room to-night to express our respect and esteem for Dr. Henderson and to show our appreciation of his valuable services as our lodge surgeon during the long period of twenty-five years past. We have good reasons for regarding medical men as the greatest benefactors of our race. They are summoned to our aid in the greatest emergencies of life, when we are stricken down by disease and brought face to face with death. They employ for our benefit their knowledge and experience, their skill and remedies, and above all they put forth their energies to heal us of the evils which flesh is heir to, and do all in their power to alleviate our sufferings. If the old proverb is at all reliable, "a friend in need is a friend indeed," then the medical man is one of our truest friends. Their noble profession is second only to that of the clergy, who are entrusted with the care and cure of immortal souls. Its very importance renders it an arduous and most anxious task. The medical man is supposed to be always on duty. His patients require his services at all hours of the day and night. He cannot make sure of any time to call his own, not even for necessary sleep or recreation. He is debarred from sharing the benefits of the eight hours' system, which are now enjoyed by many of our working men. The drain upon his time is continuous and severe and that upon his patience is equally trying and exhausting. He has many various tempers to bear with, but he is expected to dispense with his own temper both in the surgery and in the sick room. He must meet the most unreasonable patient with a smiling face and calm demeanour. The demands made on the time and patience of the clergy are trying enough, but they are few and small in comparison with those which fall to the lot of the physician. The good services of the medical man are essential to the well-being of society in general, but especially to that of institutions like our own, which have been established to give a helping hand to suffering brothers in the time of adversity and affliction. The most anxious part of the work of our society falls to the lot of the lodge surgeon, who is called upon to attend us in the time of sickness and danger. However much we may boast of our independence of the medical profession when we are in good health we are glad to acknowledge our dependence upon it and to claim its good services in time of illness. Dr. Henderson, the reverend chairman went on to say, spared neither time nor trouble in helping members when they were ill and all alike admired and esteemed his good qualities and faithful services. He would ask Dr. Henderson to accept the silver waiter which he handed him, for which 150 members had subscribed as a slight token of their esteem and respect.

The salver bore the following inscription: "Presented to J. B. Henderson, Esq., M.D., by the members of the Loyal Ancient Abbey Lodge, No. 2632, Waltham Abbey District Independent Order of Oddfellows, as a token of their esteem for his twenty-five years' valuable services as surgeon.—Oct. 27th, 1898." Dr. Henderson's health having been enthusiastically drunk he thanked the members very warmly for their kindness and the proceedings terminated with a concert. Our account of the proceedings is taken from the *Waltham Abbey Weekly Telegraph*.

ISOLATION HOSPITAL ACCOMMODATION BY COUNTY COUNCILS.

THE Isolation Hospitals Act, 1893, has not up to the present time proved in application altogether a success, in spite of the fact that it confers upon county councils very considerable powers as to isolation accommodation. The district councils are obviously not anxious to call into operation the provisions of the Act, and it cannot be said that county councils have, in the main, taken up a very strong position in the matter of enforcing the powers conferred upon them. The Act in question is certainly not an ideal one, but it is to be hoped that some means may be found to make it answer its purpose in a more satisfactory manner than has hitherto been the case. The Staffordshire County Council are evidently bent on gentle persuasion, coupled with substantial pecuniary assistance, rather than on compulsion, and if they are able by this means to bring about a proper system of isolation, ambulance provision, disinfection, and nursing in the county, all should be satisfied. Compulsion is an unpopular measure, more particularly when popularly elected councils are in question.

That there is, in very many cases at least, considerable advantage to be derived from joint hospitals goes at the present day almost without saying. There should be by this method economy in construction and economy in administration; but, above all, there should be efficiency in both, and a maintenance of that attractiveness which should be ever present in a properly managed fever hospital. There is, however, with joint hospital schemes, as with separate schemes, the financial difficulty—a difficulty which will always prove a stumbling-block where the ratepayers' representative is to the fore; and although to some extent this element is, with a growing popular appreciation of the monetary value of prevention, a diminishing one, any scheme which can offer financial assistance is bound to receive respectful consideration.

It is doubtless with a due appreciation of this aspect of the question that Dr. George Reid, the medical officer of health of Staffordshire, has recently presented a proposal to the council to contribute an annual sum of some £5600 out of the county funds towards the maintenance of isolation accommodation in the county. Dr. Reid estimates that in order to properly equip the whole administrative county some 640 beds are necessary, and deducting from this total 144 of the existing beds which can be regarded as satisfactory, there remain 496 to be provided for. The cost per bed, exclusive of site and furniture, is estimated at £230 and, allowing a certain sum for alterations of existing accommodation, it is thought that about £116,000 will be required. The annual establishment and maintenance charges, exclusive of interest on capital, is put at £16,800, and the county council has apparently agreed provisionally to contribute *annual grants* of about £5600 towards the establishment and maintenance expenses.

This is a liberal bid towards bringing the local authorities into line on the isolation question, and although the bestowal of the grant would in each case be dependent upon satisfactory provision, the local authorities will probably take the proposal into their very serious consideration, and other county councils will watch the development of it with interest and curiosity. Doubtless a comprehensive proposal such as this will not be carried out without some friction, but local authorities should remember that they can appeal to the Local Government Board against any grouping of districts which they may consider to be unfair, and this fact alone should give them confidence to discuss the matter freely. Too much time is often lost in schemes of this nature by what may be called the sulking of some local authorities.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN thirty-three of the largest English towns 6910 births and 3706 deaths were registered during the week ending Nov. 12th. The annual rate of mortality in these towns, which had declined in the nine preceding weeks from 24·6 to 17·0 per 1000, rose again last week to 17·2. In London the rate was 16·3 per 1000, while it averaged 17·9 in the thirty-two provincial towns. The lowest death-rates in these towns were 11·3 in Croydon, 11·6 in Sunderland, 11·9 in Derby, and 12·4 in Burnley; the highest rates were 21·5 in Norwich and in Manchester, 22·5 in Swansea and in Liverpool, 22·6 in Gateshead, and 23·3 in Preston. The 3706 deaths in these towns included 411 which were referred to the principal zymotic diseases, against 456 and 420 in the two preceding weeks; of these, 96 resulted from "fever" (principally enteric), 85 from diarrhœa, 77 from diphtheria, 71 from measles, 42 from scarlet fever, and 40 from whooping-cough. No fatal case of any of these diseases occurred last week in Croydon; in the other towns the lowest zymotic death-rates were recorded in Cardiff, Leicester, Birkenhead, and Huddersfield, and the highest rates in Leeds, Newcastle-upon-Tyne, Sheffield, Nottingham, and Swansea. The greatest mortality from measles occurred in

Digitized by Google

Portsmouth, Plymouth, Nottingham, Blackburn, and Sunderland; from scarlet fever in Derby; from whooping-cough in Swansea, Preston, and Halifax; and from "fever" in Norwich, Blackburn, Leeds, Sheffield, and Hull. The 77 deaths from diphtheria included 31 in London, 9 in Swansea, 8 in Leeds, 6 in Sheffield, 4 in West Ham, and 3 in Newcastle-upon-Tyne. No fatal case of small-pox was registered last week in any of the thirty-three large towns, and no small-pox patients were under treatment in any of the Metropolitan Asylums Hospitals. The number of scarlet fever patients in these hospitals and in the London Fever Hospital on Saturday last, Nov. 12th, was 3188, against 2915, 3031, and 3092 at the end of the three preceding weeks; 340 new cases were admitted during the week, against 381, 336, and 318 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 263 and 237 in the two preceding weeks, rose again to 248 last week, but were 157 below the corrected average. The causes of 52, or 1·4 per cent., of the deaths in the thirty-three towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Bristol, Nottingham, Bradford, Hull, Newcastle-upon-Tyne, and in fifteen other smaller towns; the largest proportions of uncertified deaths were registered in Wolverhampton, Birmingham, Liverpool, Manchester and Sheffield.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 20·0 and 18·9 per 1000 in the two preceding weeks, rose again to 19·4 during the week ending Nov. 12th, and exceeded by 2·2 per 1000 the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 14·5 in Greenock and 15·3 in Perth to 19·9 in Glasgow and 23·7 in Dundee. The 584 deaths in these towns included 28 which were referred to diarrhœa, 16 to "fever," 11 to measles, 11 to diphtheria, 11 to whooping-cough, and 9 to scarlet fever. In all, 86 deaths resulted from these principal zymotic diseases, against 73 and 80 in the two preceding weeks. These 86 deaths were equal to an annual rate of 2·9 per 1000, which was 1·0 above the mean rate last week from the same diseases in the thirty-three large English towns. The deaths referred to different forms of "fever," which had been 9, 15, and 16 in the three preceding weeks, declined to 16 last week, of which 12 occurred in Glasgow and 4 in Paisley. The 11 fatal cases of measles showed a further increase upon recent weekly numbers, and included 4 in Glasgow and 4 in Aberdeen. The deaths from diphtheria, which had increased from 6 to 10 in the three preceding weeks, further rose to 11 last week, of which 5 occurred in Aberdeen and 3 in Glasgow. The 11 fatal cases of whooping-cough exceeded by 4 the number in the preceding week, and included 7 in Glasgow. The deaths from scarlet fever, which had been 4 and 6 in the two preceding weeks, further rose to 9 last week, of which 5 occurred in Glasgow, 2 in Edinburgh, and 2 in Dundee. The deaths referred to diseases of the respiratory organs in these towns, which had been 119 and 128 in the two preceding weeks, were 129 last week, and were 32 below the number in the corresponding period of last year. The causes of 27, or nearly 5 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 26·4 and 24·8 per 1000 in the two preceding weeks, rose again to 30·0 during the week ending Nov. 12th. During the past four weeks the death-rate in the city has averaged 26·8 per 1000, the rate during the same period being 16·5 in London and 18·3 in Edinburgh. The 201 deaths registered in Dublin during the week under notice showed an increase of 35 upon the number in the preceding week, and included 22 which were referred to the principal zymotic diseases, against 13 and 18 in the two preceding weeks; of these, 8 resulted from diarrhœa, 5 from "fever," 4 from whooping-cough, 3 from scarlet fever, 2 from diphtheria, and not one either from small-pox or measles. These 22 deaths were equal to an annual rate of 3·3 per 1000, the zymotic death-rate during the same period being 1·4 both in London and in Edinburgh. The deaths referred to different forms of "fever," which had been 4 and 3 in each of the two preceding weeks, rose again to 5 last week. The 4 fatal cases of whooping-cough and the 3 deaths from scarlet fever showed a further increase upon those recorded in recent weeks. The fatal cases of diphtheria, which had been 3 in each of the two preceding weeks, declined to 2 last week. The 201 deaths in Dublin last week included 60 of infants under one year of age, and 45 of persons aged upwards of sixty years; the deaths both of infants and of elderly persons exceeded those recorded in the preceding week. Eleven inquest cases and 9 deaths from violence were registered; and 64, or nearly a third, of the deaths occurred in public institutions. The causes of 11, or more than 5 per cent., of the deaths in the city last week were not certified.

VITAL STATISTICS OF LONDON DURING OCTOBER, 1898.

IN the accompanying table will be found summarised complete statistics relating to sickness and mortality during October in each of the forty-three sanitary areas of London. With regard to the notified cases of infectious diseases in the metropolis, it appears that the number of persons reported to be suffering from one or other of the nine diseases specified in the table was equal to 11·5 per 1000 of the population, estimated at 4,504,766 persons in the middle of this year. In the three preceding months the rates had been 8·1, 6·5, and 8·9 per 1000 respectively. Among the various sanitary areas the rates were considerably below the average in Kensington, St. George Hanover-square, St. James Westminster, Marylebone, St. Giles, St. Martin-in-the-Fields, and Strand; while they showed the largest excess in Fulham, Hackney, Holborn, Clerkenwell, St. Luke, Newington, Bermondsey, Battersea, and Plumstead. Not one case of small-pox was notified in London during October, the numbers in the three preceding months having been 2, 5, and 2 respectively; and no small-pox patients were under treatment last month in any of the Metropolitan Asylum Hospitals. The prevalence of scarlet fever in London showed a considerable further increase upon that recorded in recent months; among the various sanitary areas this disease showed the highest proportional prevalence in Fulham, Islington, Hackney, Holborn, Clerkenwell, St. Luke, Newington, Bermondsey, and Plumstead. The Metropolitan Asylum Hospitals contained 2977 scarlet fever patients at the end of October, against 2255, 2207, and 2425 at the end of the three preceding months; the weekly admissions averaged 350, against 242, 202, and 270 in the three preceding months. The prevalence of diphtheria in London during October showed an increase upon that recorded in the two preceding months; this disease was proportionally most prevalent in Fulham, Holborn, St. Luke, Newington, Bermondsey, Battersea, Greenwich, and Lee sanitary areas. There were 1182 diphtheria patients under treatment in the Metropolitan Asylum Hospitals at the end of October, against 1014, 865, and 1024 at the end of the three preceding months; the weekly admissions averaged 172, against 146, 107, and 163 in the three preceding months. The prevalence of enteric fever in London showed a marked further increase upon that recorded in recent months; among the various sanitary areas this disease showed the highest proportional prevalence in Westminster, Hackney, St. Martin-in-the-Fields, Limehouse, Poplar, and Greenwich. The Metropolitan Asylum Hospitals contained 223 enteric fever patients at the end of October, against 87, 118, and 155 at the end of the three preceding months; the weekly admissions averaged 41, against 16, 21, and 28 in the three preceding months. Erysipelas was proportionally most prevalent in Holborn, St. Luke, Bethnal Green, Whitechapel, and Mile End Old Town sanitary areas. The 22 cases of puerperal fever notified in London during October exceeded the number in any recent month, and included 5 in Kensington sanitary area.

The mortality statistics in the table relate to the deaths of persons actually belonging to the various sanitary areas of the metropolis, the deaths occurring in the institutions of London having been distributed among the various sanitary areas in which the patients had previously resided. During the four weeks ending Saturday, Oct. 29th, the deaths of 5983 persons belonging to London were registered, equal to an annual rate of 17·3 per 1000, against 14·7, 20·7, and 21·0 in the three preceding months. The lowest death-rates in the various sanitary areas were 7·3 in St. Martin-in-the-Fields,

12·4 in Stoke Newington, 12·5 in St. George Hanover-square, 12·9 in Hampstead, 13·8 in Lee, 13·9 in London City, and 14·0 in Wandsworth; the highest rates were 22·1 in Bethnal-green, 22·3 in Woolwich, 22·4 in Strand, 23·3 in Bermondsey, 25·6 in Holborn, 26·5 in St. George Southwark, and 27·9 in St. Luke. During the four weeks of October 677 deaths were referred to the principal zymotic diseases in London; of these, 1 resulted from small-pox, 47 from measles, 38 from scarlet fever, 150 from diphtheria, 58 from whooping-cough, 66 from enteric fever, 2 from ill-defined forms of continued fever, and 315 from diarrhœa. These 677 deaths were equal to an annual rate of 2·0 per 1000; no deaths from any of these diseases were recorded last month in Stoke Newington, St. Martin-in-the-Fields, or London City; in the other sanitary areas the lowest zymotic death-rates were recorded in Kensington, St. George Hanover-square, Hampstead, St. Giles, Rotherhithe, and Plumstead; and the highest rates in Clerkenwell, St. Luke, St. George-in-the-East, Limehouse, Mile End Old Town, St. George Southwark, and Bermondsey. The fatal case of small-pox belonged to St. George Hanover-square sanitary area and was the first death referred to this disease in the metropolis since August, 1897. The 47 deaths referred to measles were 75 below the corrected average number in the corresponding periods of the ten preceding years; this disease showed the highest proportional fatality in St. Luke, Bethnal Green, Mile End Old Town, and St. Saviour Southwark sanitary areas. The 38 fatal cases of scarlet fever were less than half the corrected average number; among the various sanitary areas this disease was proportionally most fatal in Clerkenwell and St. Luke. The 150 deaths from diphtheria were 58 below the corrected average number; this disease showed the highest proportional fatality in Paddington, Fulham, Limehouse, Mile End Old Town, Poplar, St. George Southwark, Bermondsey, Battersea, and Lewisham sanitary areas. The 58 fatal cases of whooping-cough were 23 below the corrected average number; among the various sanitary areas this disease was proportionally most fatal in Westminster, Bermondsey, and Lee. The 66 deaths referred to enteric fever were slightly below the corrected average number; this disease showed the highest proportional fatality in Hampstead and Greenwich sanitary areas. The 677 fatal cases of diarrhœa were 138 above the corrected average number; among the various sanitary areas this disease showed the highest proportional fatality in Clerkenwell, St. Luke, St. George-in-the-East, St. George Southwark, and Newington. In conclusion, it may be stated that the aggregate mortality in London last month from these principal zymotic diseases was 10 per cent. below the average.

Infant mortality in London during October, measured by the proportion of deaths of children under one year of age to registered births, was equal to 158 per 1000. Among the various sanitary areas the lowest rates of infant mortality were recorded in Marylebone, Hampstead, Stoke Newington, St. Martin-in-the-fields, London City, and St. Olave Southwark; and the highest rates in St. James Westminster, Holborn, Clerkenwell, Shoreditch, Bethnal Green, Bermondsey, and Plumstead.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments are notified:—Surgeons: John Boyan, W. H. Daw, Cyril Shepherd, Hugh L. Norris, Adrian A. Forrester, James M. G. Swainson, John Stoddart, James A. Forrest, Warren G. Westcott, Francis J. McKenna, Fairman R. Mann, William W. Keir, Edward C. Sawdy, Percy H. Bannister, Richard S. Osborne, Mervyn W. Falkner, Edward O. B. Carberry, John K. Raymond, and Henry W. M. Rees, to the *Victory*, for Haslar Hospital.

ROYAL ARMY MEDICAL CORPS.

Captain Tate and Lieutenant Penny are held in readiness for service in West Africa. Major Woods is posted to the Dublin District for duty pending embarkation for Egypt. Lieutenant-Colonel Somerville-Large is transferred from the Dublin District to the charge of the hospital for soldiers' wives and children at Portsmouth. Lieutenant O'Gorman is placed under orders for service in South Africa. Captain Henry Vincent Dillon retires from the Service receiving a gratuity.

INDIA AND THE INDIAN MEDICAL SERVICES.

Major W. Dugdale, R.A.M.C., is transferred from Bombay to the Nagpore District. Captain R. H. Castor, Civil Surgeon, Akyab, has been granted furlough for two years from the date on which he may avail himself of it. Lieutenant-Colonel Joshua Duke, Medical Officer, Bhopawar Political Agency, is appointed to succeed Colonel Deane as Residency Surgeon, Kashmir. Lieutenant-Colonels Charlton, R.A.M.C., and P. F. O'Connor will be the Principal Medical Officers of the Northern and Southern Divisions respectively at the cavalry camp of exercise in January. Lieutenant-Colonel E. H. Fenn, C.S.I., R.A.M.C., doing duty at Peshawur, is appointed Surgeon on the Staff of Lord Curzon of Kedleston, and will join on the Governor-General's arrival in India.

VOLUNTEER CORPS.

Artillery: 1st Banff: William Donald to be Surgeon-Lieutenant. 1st Cumberland: Surgeon-Captain J. Little to be Surgeon-Major. 2nd Middlesex: Surgeon-Lieutenant A. B. Lyon, from the 1st Banff Volunteer Artillery, to be Surgeon-Lieutenant. *Rifle:* 3rd Lanarkshire: Surgeon-Lieutenant-Colonel J. Dunlop. 1st Volunteer Battalion the Worcestershire Regiment: Surgeon-Lieutenant J. Robinson to be Surgeon-Captain. 1st Volunteer Battalion the East Lancashire Regiment: Surgeon-Lieutenant W. Moir resigns his commission. 1st (City of Dundee) Volunteer Battalion the Black Watch (Royal Highlanders): Surgeon-Captain J. M. Whyte resigns his commission. 21st Middlesex (the Finsbury): Surgeon-Lieutenant E. Jones to be Surgeon Captain. 4th (Donside Highland) Volunteer Battalion the Gordon Highlanders: Surgeon-Lieutenant J. O. Wilson to be Surgeon-Captain. 6th Volunteer Battalion the Gordon Highlanders: Surgeon-Lieutenant-Colonel R. S. Turner resigns his commission; also is permitted to retain his rank, and to continue to wear the uniform of the battalion on his retirement.

THE SOUDAN GAZETTE.

We print below some of the awards for service during the recent campaign in Egypt. It will be noticed that we depart somewhat from our usual custom of recording in this column the names of members of the medical profession alone and include the Army Veterinary Department, the rank and file of the Royal Army Medical Corps, and nurses:—To be Ordinary Members of the Military Division of the Third Class, or Companions of the Most Honourable Order of the the Bath: Surgeon-General William Taylor, A.M.S., and Colonel William Henry Macnamara, R.A.M.C. To be Members of the Distinguished Service Order: Lieutenant-Colonel George Arthur Hughes, R.A.M.C.; Major Edmond Munkhouse Wilson, C.M.G., R.A.M.C.; Major Hugh Broderick Mathias, R.A.M.C.; and Captain Charles Stuart Spong. *Brevet:* Lieutenant-Colonel T. J. Gallwey, C.B., Principal Medical Officer, Egyptian Army, to be Colonel; Major G. W. Robinson to be Lieutenant-Colonel; Captain R. H. Penton, D.S.O., employed with the Egyptian Army, to be Major; Captain H. E. H. Smith, employed with the Egyptian Army, to be Major; Lieutenant E. W. Bliss to be Captain; and Veterinary-Lieutenant T. E. W. Lewis, employed with the Egyptian Army, to be Veterinary Captain. The Medal for Distinguished Conduct in the Field has been granted to the under-mentioned: Royal Army Medical Corps: First Class Staff-Sergeant Hoist, Sergeant F. Crooke, Sergeant G. A. Benson, Sergeant Scrase, Lance-Sergeant A. P. Mears, and Private A. Davidson. The under-mentioned officers are granted the next higher rates of pay of their rank: Lieutenant-Colonel A. T. Sloggett, Royal Army Medical Corps, and Veterinary-Captain G. R. Griffiith, D.S.O., Army Veterinary Department. The Queen has conferred the Decoration of the Royal Red Cross upon the under-mentioned nurses in recognition of their services in tending the sick and wounded: Miss Sarah Emily Webb, Army Nursing Service; Miss Amy Florence Grist, Army Nursing Service; and Miss Elizabeth Geddes, National Society for Aid to Sick and Wounded in War.

THE ROYAL NAVAL EXAMINATIONS.

The under-mentioned gentlemen, who competed on Oct. 31st and following days at the Examination Hall,

Gratuities to British Troops in the Soudan.

A gratuity is to be issued to the British troops engaged in the recent operations in the Soudan. Every officer, warrant officer, non-commissioned officer, and other soldier of such troops who was employed south of Wady Halfa will be entitled to participate in the grant. The gratuity will also be issued in special cases upon the recommendation of the general officer commanding in Egypt to certain officers and men who were employed at Wady Halfa and Assouan. The unit of the scale will be £3 in the case of those who took part in both the battles of the Atbara and of Khartoum and £1 10*s.* in all other cases.

The Medical Department of the German Navy.

According to the project that was passed by the Reichstag last year the German Navy, which, without reckoning torpedo boats, training ships, special service vessels, and gunboats, consisted in 1897 of 12 ships of the line, 8 armoured coast protectors, and 33 cruisers, should in 1904 be constituted as follows: 19 ships of the line, 8 armoured coast protectors, 12 cruisers of the first class, and 30 cruisers of the second class, being an increase of 16 fighting units, or 30 per cent. This augmentation will entail the addition of 8839 officers and men to the strength, which will thus be increased from 18,898 to 27,737 of all ranks, an increment equal to 46·7 per cent. The scheme for the Medical Department provides for an additional *personnel* equal to rather more than 49 per cent., the total number of medical officers being increased from 122 to 182. The relative strength in the various grades is shown below:—

	1897.	1904.
Surgeon-General	1	1
Station surgeons	2	2
Staff surgeons...	17	33
Surgeons	45	67
Assistant surgeons	57	79
Total	122	182

Lord Kitchener and the Grenadier Guards.

Lord Kitchener of Khartoum recently distributed the Soudan medals, which had been struck by order of the Egyptian Government, to the Grenadier Guards at Wellington Barracks, where between 500 and 600 men were paraded for the purpose, but some 80 men were absent owing to their being sick in hospital. His lordship therefore subsequently proceeded to the Guards' Military Hospital at Rochester-row and there distributed the medals to the non-commissioned officers and men on the sick-list—86 in all we believe—to several of whom the General made a few congratulatory remarks.

Pasteur Institute for India.

Some idea of the need for the establishment of a Pasteur Institute in India may be formed from the fact that since July 1st no less than nineteen British soldiers, the *Times of India* states, have been sent to Paris for treatment at the estimated cost of about 1000 rupees per head. We hope to see the day when there will be an institute, furnished with a bacteriological laboratory and all appliances for the scientific investigation of the diseases of India, in each of the three Presidencies. Some institution of this kind might well form part of a sanitary or public health department for India.

Deaths in the Services.

Brigade-Surgeon Frederick Pennington, (retired), A.M.S., at Lugano on Nov. 4th in his 69th year. He joined the army in 1858, became Surgeon in 1873, Surgeon-Major in 1873, and retired with the honorary rank of Brigade-Surgeon in 1885. He served in the Indian Mutiny, 1858–59 (medal), in the Ashanti War, 1873–74 (medal), and in the Egyptian expedition, 1882 (medal and Khedive's star).

THE EPIDEMIC OF TYPHOID FEVER AT BELFAST.

SECOND YEAR.

(From our Special Commissioner.)

The number of cases of typhoid fever notified last year as occurring in the town of Belfast amounted to 3269. This was a severe lesson; but, as a new town council had been elected and many of the successful candidates were pledged to a programme of energetic sanitary measures, it was only natural to hope that these effective reforms would at once be realised. Far be it from me to say that nothing has been done, but whatever was attempted has certainly proved ineffectual, for there has been another and equally severe epidemic. During the four weeks ending July 16th of the present year 226 cases of typhoid fever were notified. In the following four weeks, ending on August 20th, 784 cases were notified. The climax was reached during the ensuing four weeks when 1121 cases were notified. After this the epidemic showed signs of abatement though there were still many cases—namely, 636 notifications from Sept. 18th to Oct. 15th last. During the two weeks following this last date there were 125 and 98 more notifications, but it is now stated that the epidemic seems to be drawing to an end. In any case we have here the record of 2990 cases occurring in 18 weeks and this cannot be considered an improvement on the 3269 cases notified during the 52 weeks of last year. Yet, and in spite of this repeated and appalling lesson, entailing such widespread suffering and the loss of so many lives, strenuous efforts are still made to prevent the enforcement of those sanitary reforms which are obviously necessary. During the epidemic last year I described at length the sanitary defects of the town of Belfast. Apart from the main drainage system, which is defective, I pointed out that the more urgent grievance was the presence of numerous and foul privies. In his report for the year 1897 which was issued this week the superintendent medical officer of health, Dr. Henry Whitaker, states that he examined the condition of 2211 houses where cases of typhoid fever had occurred. Of these, 352 had privies with back passages and 750 had privies without back passages; therefore, to remove the excreta from these latter houses it had to be carried through the ground-floor rooms of the house. This means a back bedroom, scullery, wash-house or pantry, and the front room, which is generally the parlour, the living room, and the place where all the cooking is done. The contents of these privies is simply shovelled out into buckets. Some of it is often spilt inside the house as it is carried through to reach the street. In thus stirring up this foul matter, abominable odours arise. The gases liberated permeate the entire house, are absorbed by milk and whatever other articles of food may be about, and these may also receive particles of dust, &c., that have been in contact with the dejecta removed. It is not surprising that such houses are more liable to typhoid fever than those which drain into water-closets. Dr. Whitaker calculates that whilst typhoid fever has occurred in 2·7 per cent. of the houses having water-closets it has occurred in 5·5 per cent. of the houses having privies, and we have seen that among the privy houses by far the greater number of cases were found to be in the houses which have no back passages.

The figures which Dr. Whitaker gives concerning the injurious effect of the privy system are fully confirmed by the calculations of the medical officers of health of other towns. For instance, Dr. Charles Porter, medical officer of health of Stockport, shows that during the last five years the incidence of typhoid fever in the water-closet houses in that town was equal to 1·21 per cent., while that in privy-pit houses was equal to 3·39 per cent.[1] Nevertheless, and in spite of these most conclusive facts, on Nov. 2nd the town council held its quarterly meeting, and the discussion was prolonged for three days. One of the chief subjects debated was a Bill to be introduced into Parliament in order to obtain money and powers to carry out various improvements. Before the opening of the business proceedings a deputation waited on

Digitized by Google

the council headed by Mr. J. B. Dunlop, probably the largest owner of workmen's cottages and also of a better class of property in Belfast. In the name of the deputation he objected to the increase of taxation which the proposed Bill would entail. As against the compulsory application of the water-closet system he urged that the system of "dry closets" was the proper one, as was shown by the fact that he had hundreds of houses so supplied and not a case of typhoid fever had occurred in any of them. He did not wish to threaten, but he forcibly pointed out that the Bill would meet with strenuous opposition. In reply the Lord Mayor said that some members of the Corporation were in favour of the "dry closet system," but that the majority of the Corporation thought the system was one impossible of being properly worked.

What seems to me to be misleading in the above is the use of the term "dry closet." The danger, on the contrary, rests in the fact that these closets are wet, reeking with liquid and concentrated sewage that soaks into the subsoil, that oozes through the brick walls, and in some cases even penetrates into the dwelling portion of the houses. Anyone taking up a text-book on sanitation or reading the opinion of some well-known authority on the subject would find that a great deal has been said in favour of dry closets such as Moule's patent earth-closets. But the secret of such merit depends on the absolute dryness of these closets and the frequent, almost daily, removal of their contents. Dry closets, however, are impracticable in a town. They require an immense amount of attention. The constant removal of the metallic pails, the ample provision of carefully prepared, dried, and broken-up earth, cinders, or ash would all cost very much more than water-closets. Where in country districts it is not possible to provide sewers to drain water-closets the dry-earth system is an excellent way out of the difficulty, but it is quite impracticable in large towns. At Manchester it has been applied for many years at a great expense and with the display of much ingenuity and care; still Manchester is giving up the system and introducing water-closets in its stead. But the dry-pail system of Manchester cannot be compared for a moment with the plague-promoting wet privies of Belfast. It will be seen that the use of the term "dry closet" is most misleading. It would be quite unjustifiable to utilise the well-known arguments that have been adduced in various countries in favour of dry closets to defend the wet privy-pits of Belfast. Under these circumstances it is regrettable that the term "dry closet" has come into general use in Belfast, for in this town at least it is altogether a misnomer.

Fortunately, it is generally recognised that the privies, whether qualified as dry or wet, must be done away with. It is also admitted that passages must be provided behind all the houses, even though through the introduction of water-closets these passages would serve to remove the contents of the dustbins only, and not as at present fæcal matter. But these measures still meet with strenuous resistance even within the town council. The opponents of sanitary improvement, it is true, have almost ceased to argue the question, but they punctually attend committee meetings of the corporation and record a silent though solid vote against sanitary reforms. Councillor Dr. O'Connell did not hesitate to denounce this proceeding at the public general meeting of the town council. This arose on the question of testing drains. Out of eight aldermen six had voted against such a measure and the two other aldermen abstained from voting. Dr. O'Connell protested that there were too many aldermen on the Public Health or Improvement Committees. Councillor Liddell also complained that proceedings were not instituted to enforce the making of back passages and the introduction of water-closets. He urged that the town council should set a good example by prosecuting some of its own members. Councillor Magee pointed out that the Public Health Committee had resolved to institute proceedings against a house where the privy was in a very bad condition and where there was no back passage, and they recommended the landlord to put in a water-closet. On the other hand, the Improvement Committee had recently approved plans for the erection of new houses where there would be neither water-closet nor back passages. Thus one committee prosecutes for what the other committee sanctions. By some piece of good fortune this particular instance has not slipped by unperceived and the owner has now undertaken to provide a back passage and water-closets.

With regard to domestic drainage a resolution had been passed to the effect that all water-closet drains in the town should be tested. Thereupon it had been argued that this would necessitate the employment of an extra staff of thirty-nine sanitary inspectors. This argument was well calculated to frighten the timorous ratepayer. Another objection was raised, not this time for the purpose of obstruction, but rather with the view to defend trade union interests. The labour members of the council urged that the inspectors appointed to test the drains should be fully-qualified plumbers. They seemed to think that men who had no particular trade could be secured for a salary of 25*s*. a week, whereas a plumber would have to be paid a much higher wage. A good deal was said about the incompetence of cheap inspectors. These objections seem outside the mark. A plumber would be very useful inside a house, but outside the house, and especially where brick drains had been laid, a bricklayer would be better qualified. The real fact is, however, that what is wanted is neither a bricklayer nor a plumber but a much larger and a more efficient staff of carefully-trained and fully-qualified inspectors of nuisances. For the moment the examination of house-drains and plumbers' work may take up most of the time of such inspectors; but there is other sort of work to be done of a totally different nature for which a man who is only a plumber would be absolutely incompetent. It was ultimately decided that seven extra sanitary inspectors with assistants should be appointed subject to the approval of the Local Government Board. Considerable vigilance will, however, have to be exercised to see that thoroughly qualified men are appointed to these posts and that they are paid a proper salary. Here the labour representatives on the town council will be acting in harmony with their principles and programme if they see that "blackleg" sanitary inspectors, who are incompetent but willing to accept less than the usual salary, are not selected in preference to properly qualified and properly paid inspectors. A plumber is not an inspector of nuisances and has not received the proper training. Last year the old municipal boundary, which comprised 3806 acres, was extended to the surrounding suburban districts, so that it now consists of 16,503 acres. The added portions only contain 23,000 inhabitants, though the medical officer of health considers this figure is not correct, and that 30,000 would be nearer the truth. However this may be, as the number of inhabitants within the old boundary is now set down at 310,000 it will be seen that the population in the vast and newly added districts must be very much scattered. The work of sanitary inspection among these people will consequently take much time, and this is another reason for considerably increasing the sanitary staff.

(To be continued.)

BIRKENHEAD AND DISTRICT NURSES' FUND: VISIT OF H.R.H. PRINCESS CHRISTIAN OF SCHLESWIG-HOLSTEIN.—H.R.H. Princess Christian was present at a meeting held at Birkenhead in connexion with the Birkenhead and District Nurses' Fund on Nov. 3rd. The object of the meeting was to bring before the public the work done by the Birkenhead and District Nursing Society. In the autumn of last year the society became affiliated with the Victoria Jubilee Nursing Institute and in February last the institute sent down two nurses who began local work on Feb. 10th. In July two other nurses were added in spite of the small amount of subscriptions which had come in, but as the society had received a promise of £300 from the Jubilee Institute the committee considered their action to be justifiable. The rules of the Birkenhead Society are practically similar to those of the Queen's Institute and the work is carried on upon unsectarian lines. Up to the present time 213 cases have been attended with a total of 6448 visits. During the month of October 1163 visits were paid. The subscriptions collected this year have so far amounted to £147 13*s*. 6*d*. and the donations to £26 2*s*. 6*d*., the total amount having been £435 5*s*. It is satisfactory to find that after paying expenses there is a balance in hand of £233 4*s*. 5*d*. Her Royal Highness was accorded a hearty vote of thanks for the interest which she had taken in the society and which it is hoped will act as a stimulus in enlisting the sympathy of the public in aid of its charitable objects.

Obituary.

WILLIAM CAMPBELL MACLEAN, C.B., LL.D., M.D. EDIN.,

SURGEON-GENERAL, I.M.S.; LATE PROFESSOR OF MEDICINE IN THE ARMY MEDICAL SCHOOL AND HONORARY SURGEON TO THE QUEEN.

WE regret to announce the death of Surgeon-General Maclean, which took place on Nov. 10th, at Sidmouth, Devonshire, whither he had gone hoping to be benefited by the mildness of the climate.

William Campbell Maclean was born on Nov. 29th, 1811, at Blackburn House, in Ayr, and was of Highland descent through both his paternal and maternal ancestors. His father was the representative of the family known as the Macleans of Boreray (the first branch of the Macleans of Ardgour in Argyllshire) and had early in this century purchased the estate of Drimnin, in Morvern, on the Sound of Mull, from Macdonald of Glenaladale. His mother was the youngest daughter of Donald Macleod of Bernera, in the county of Inverness. The subject of this notice was their tenth child and youngest son, and was named after his father's bosom friend, William Campbell of Ainsay, Colonel of the 78th Highlanders, who in 1811, the year of the future Surgeon-General's birth, fell at the head of his regiment at the capture of Java.

About the year 1818 the family moved to Edinburgh and took up their residence at Deanbank House, near Stockbridge. In the year 1824 young Maclean was sent to Dollar Academy in Clackmannanshire and afterwards to Edinburgh Academy, in 1829 he commenced the study of medicine in Edinburgh University, in 1832 he became a Licentiate of the Royal College of Surgeons of Edinburgh, and in 1833 he graduated as M.D. at the University.

In the autumn of 1833 his uncle, Sir John Macleod, informed him that Sir John Keene (afterwards Lord Keene of Gaznee) had been appointed Commander-in-Chief of the Bombay Army and that he was posted surgeon of the ship *Upton Castle*, in which his Excellency was to sail for that presidency and in which he embarked in November of that year. After a second voyage to the East, made in 1836 on board the *Marquis Camden*, he returned to England, and spent the winter of 1836-37 in Paris visiting the hospitals, pursuing the study of anatomy and natural history, and attending the lectures of Andral on general medicine and the clinique of Chomel, who was then considered the most distinguished clinical teacher in France. Dr. Maclean's commission of Assistant Surgeon in the Madras Army is dated April 15th, 1838. Proceeding to India on board the *Orwell* he landed at Madras and entered on his probationer course in the General Hospital under Dr. Mortimer, the senior physician to that institution. After two months' duty he received orders to embark in a transport for Masulipatam, there to ship a native infantry regiment for Moulmein in Burma, and to return with the relieved regiment, the 13th, to Madras.

WILLIAM CAMPBELL MACLEAN, C.B., LL.D., M.D. EDIN., SURGEON-GENERAL, I.M.S.

On arrival at Madras his regiment was ordered to the station of Palaveram, near St. Thomas's Mount, where Dr. Maclean remained in medical charge until relieved by a senior medical officer just arrived from England. After leaving the 13th he was ordered to proceed to Secunderabad in the Deccan to do duty with the 55th regiment, and as there was no combatant officer available for the duty some young officers recently arrived in India were placed under his authority, under a special order by the Commander-in-Chief, until they should complete the march to that station. The 55th was then under the command of Colonel Schoede, a Peninsular veteran, Dr. Shanks being the surgeon of the regiment.

Early in 1839 a wing of the 55th regiment was ordered to Madras and Dr. Maclean was placed in medical charge of it, but on arrival at the presidency town he was posted to the charge of the Queen's Garrison Hospital by Dr. John Murray, Inspector-General of Queen's troops. After holding this appointment at Madras for three months it became known that, consequently on the high-handed proceedings of Commissioner Lin in destroying opium the property of British merchants, and in interference with British trade, contrary to treaty engagements, an expedition was preparing against China, and Madras was to furnish the artillery and engineers. Dr. Maclean volunteered, his services were accepted and he sailed on the *Rustomjee Cowasjee* on April 14th, 1840, with the two companies of artillery, under Colonel Peter Montgomerie, C.B., to which he was attached for duty. He served in China until the end of the war and was mentioned in despatches. He was present at the first capture of Chusan; at all the operations in the Canton River and heights above the city; at the bombardment and capture of Amoy; at the second capture of Chusan; at the battle of Chinhai, the occupation of Ningpo, and the repulse of the enemy from that place; at the battle of Chapu; at the heights of Segoan; at the bombardment of Woosung, and the other operations on the Yang-tzi-Kiang River; and at the battle of Chin-Kiang-Foo. In these operations he was for the most part attached to the 18th Royal Irish Regiment, and was responsible for all the medical duties of the regiment in the field during this arduous service, the surgeon of the regiment having been laid aside by ill-health. During these operations he was five times employed with the advanced guard, and on three occasions landed with attacking troops under fire. At the battle of Chapu he assisted in carrying out Colonel Tomlinson, of the 18th Royal Irish, from the passage in the building which was defended by a brave body of Tartar soldiers, where he had been mortally wounded. He died in Dr. Maclean's arms within a few minutes. At the capture of Chin-Kiang-Foo Captain Collinson fell into Dr. Maclean's arms as he dropped dead from a ball in his heart, and a few minutes afterwards, when dressing a wounded officer of the same regiment (the 18th), Dr. Maclean was nearly killed by a ball which, striking the parapet a few inches above his head, covered him and the wounded officer with the débris of the broken wall. Taking his final

Digitized by Google

leave of his gallant friends of the 18th Royal Irish on Nov. 1st, 1843, he returned to India in medical charge of the C troop of Madras Horse Artillery and served for six months at Arcot in medical charge of a wing of the 1st Madras Fusiliers.

In 1844, his services in China having been brought to the notice of the Governor-General of India by the Commander-in-Chief, Lord Gough, Dr. Maclean proceeded to Bengal and joined the camp of the Governor-General with the Army of Exercise in Central India. It was at this time that the medical service was in danger of losing one of its brightest ornaments, for on one occasion Dr. Maclean was summoned to the office of his lordship's private secretary and offered an appointment in the Mysore Commission, by order of the Governor-General, in very flattering terms. Captain (afterwards Sir) Henry Durand pressed the offer on the ground that it opened up a new career, with no inconsiderable opportunities of advancement and distinction. This offer, however, Dr. Maclean declined as it involved turning his back on a profession which he loved and, as it were, the throwing away of the years spent in its study. On his decision being known the Governor-General conferred on him the appointment of residency surgeon at the Court of Hyderabad, in the Deccan, the best appointment a man of his rank could hold in his own department of the public service. At Hyderabad he served under Major-General Stewart Fraser, Sir John Low, Mr. Bushby of the Bengal Civil Service, and Major Davidson, until the year 1855, when he vacated the appointment on promotion. Not long after joining at Hyderabad the Resident obtained the sanction of the Nizam's Government and of the Governor-General to establish a medical school at the residency with a view to educate a body of native doctors through the medium of their own language. Dr. Maclean was appointed the first superintendent of this school, an office involving much labour. This was the first vernacular school of medicine in India; the pupils were all Mahomedans. The great majority turned out remarkably well. Some entered the civil service of H.H. the Nizam and were employed in their professional capacity in various parts of his dominions, others settled as civil practitioners in the great city of Hyderabad where they attained to wealth and consideration, and, as has been repeatedly acknowledged by the Nizam's Minister, Sir Salar Jung Bahadur, have been of inestimable service to all ranks of the people. The school is still in vigorous existence. In connexion with this appointment Dr. Maclean on three occasions received the approbation of the Court of Directors of the Honourable East India Company and the thanks of the Government of India. When the time came for him to vacate his appointment on promotion Lord Dalhousie acknowledged his services in the most handsome manner in a letter to the Resident and requested him to nominate another officer as his successor. Dr. Maclean sent up three names and was by return of post requested to name one of the three. He named Dr. George Smith, who was appointed and more than justified his nomination.

In the year 1855 Dr. Maclean returned to England on medical certificate after seventeen years' continuous service, but again sailed for India early in 1857. He then served for nearly a year as garrison surgeon at Visagapatam, but towards the close of that year he was appointed medical officer of the third district of Madras, including the charge of the Military Asylum. He discharged the duties of this large division until November, 1860, when he finally embarked for England. While holding this post he was appointed by Lord Harris, the Governor of Madras, to be a Fellow of the University of Madras with a seat on the council of the governing body of the College.

When Mr. Sidney Herbert, afterwards Lord Herbert of Lea, then Secretary for War, founded the Army Medical School at the close of the Crimean war a medical officer competent to teach tropical diseases was required. The India Office was applied to, the records were searched, and the reports sent to the Court of Directors by the Government of India, based on those of the Residents at Hyderabad, led to Dr. Maclean's nomination. When appointed as Professor of Medicine in the Army Medical School he was commissioned to the home service without prejudice to the officers of that service as a deputy-inspector-general and subsequently as a surgeon-general. After a probationary trial of two years he was permanently appointed and occupied the chair for twenty-five years, first at Fort Pitt, Chatham, and afterwards at the Royal Victoria Hospital, Netley. In due course, in 1871, he was made a Companion of the Most Honourable Order of the Bath, civil division, and an Honorary Surgeon to the Queen. The University of Glasgow also conferred on him (*honoris causâ*) the degree of Doctor of Laws.
